ons in hydraulic and organic loads cause ter treatment plant operating problems, necessitating some form of process control to ensure attainment of design objectives. A comparision of in-plant control with equalization control indicates that the latter is more appropriate for the case of long sludge age nutrient removal activated sludge processes which include anaerobic, anoxic and aerobic zones. A microprocessor-based control strategy is presented for the operation of an equalization tank upstream of the process to reduce, optimally, diurnal fluctuations in both flow and organic load rates. Results from implementation on a 150 Ml/d plant with an in-line equalization tank (4,5 hour mean retention time) demonstrate the successful performance of the control strategy. (Author's abstract)

A-B PROCESS: A NOVEL TWO STAGE WASTEWATER TREATMENT SYSTEM,
ESMIL International B.V., Amsterdam (Netherlands).
A. I. Versprille, B. Zuurveen, and T. Stein.
Water, Science and Technology, Vol. 17, No. 2/3, p 235-246, 1985. 7 Fig, 8 Tab, 15 Ref.

Descriptors: *Wastewater treatment, *A-B process, Organic load, Hydrogen ion concentration, Toxic shocks, Two-step treatment, Sludge.

New acts on wastewater disposal demand for higher process stability and effluent quality. The A-B process, a novel two step treatment system, meets these requirements in a cost effective way. Five full-scale plants have been put in operation over the last two years. The objective of this paper is to give an outline of the features of the A-B system in the context of the results of these full-scale plants. In spite of the extreme high load, the A-stage can be operated at a higher reduction rate and is stable. Variations in the organic load and pH- and toxic shocks are leveled out and a constant, mainly soluble effluent is supplied. This implicates a low sludge production in the B-state. As a consequence higher overall reduction rates are obtained as compared to conventional processes at the same sludge load. Very low and stable final effluent concentrations are observed in all full-scale plants. Of special interest are the possibilities of upgrading existing conventional treatment facilities, at minor costs, by incorporating the A-B technology. The A-B process therefore can be considered as a very promising, cost effective alternative for both existing and new wastewater treatment plants in responding to the increasing effluent demands. FLEXIBLE MODELLING OF THE ACTIVATED SLUDGE SYSTEM - THEORETICAL AND PRACTICAL ASPECTS,
Environmental Protection Service, Jerusalem (Israel).
M. S. Sheffer, M. Hiraoka, and K. Tsumura.
Water, Science and Technology, Vol 17, No. 2/3, p 247-258, 1985. 10 Fig, 10 Ref.

Descriptors: *Flexible modelling, *Activated sludge process, Computer models, Algorithms, Wastewater treatment, Model studies, Mixed liquor solids.

For the purpose of optimal modelling, a 'Flexible Modelling' method was developed. A flexible set of models consisting of hierarchical mechanistic models derived from a highly detailed structured model by mechanistic simplification was obtained. The performance of a computer program with an algorithm for parameter fitting in the time domain was evaluated by use of simulation. The program was able to estimate the models' parameters, even when using data with different degrees of inaccuracy. A computer program for model selection was developed, whereby the model was selected according to the information required. It was found that for prediction of the dynamic behavior of the MLSS, the simplest model can supply all the necessary information. For prediction of effluent substrate concentration, the differences between the models' predictions depend on the characteristics of the disturbances and on the values of the models' parameters. The selection of the proper model and updating its parameters can be done by a computer which uses the presented program for model selection and parameter fitting. (Author's abstract)

DETERMINATION OF KINETIC CONSTANTS OF ACTIVATED SLUDGE MICROORGANISMS,
Vysoka Skola Chemicko-Technologicka, Prague (Czechoslovakia). Inst. of Water Technology and Environmental Protection.
J. S. Cech, J. Chudoba, and P. Grau.
Water, Science and Technology, Vol. 17, No. 2/3, p 259-272, 1985. 9 Fig, 5 Tab, 11 Ref.

Descriptors: *Activated sludge process, *Kinetics, *Microorganisms, Respirometry, Biological wastewater treatment, Substrate removal.

A method for measuring kinetic constants of activated sludge microorganisms by means of a simple respirometer was developed and tested by using two types of mixed culture. The method can be used for those substrates that cannot be easily determined analytically. It is much more sensitive than the methods based on the biomass growth or substrates removal. The method determines kinetic constants of mixed cultures at given loading and mean cell residence time without changing its qualitative and quantitative composition. Both the maximum substrate removal rate and the half-velocity coefficient are basically lower with the mixed cultures cultivated in a completely-mixed reactor (filamentous) than with those cultivated in a selector-type reactor (nonfilamentous). DEVELOPMENT OF POLLUTANT SPECIFIC MODELS FOR TOXIC ORGANIC COMPOUNDS IN THE ACTIVATED SLUDGE PROCESS,
Vanderbilt Univ., Nashville, TN. Dept. of Civil and Environmental Engineering.
A. T. Watkin, and W. W. Eckenfelder, Jr.
Water, Science and Technology, Vol. 17, No. 2/3, p 279-289, 1985. 4 Fig, 3 Tab, 15 Ref.

Descriptors: *Organic compounds, *Activated sludge process, *Model studies, Biological wastewater treatment, Phenol, Dichlorophenol, Dinitrophenol, Dinitrobenzene, Carbon tetrachloride, Volatilization, Biodegradation, Mathematical models.

The concept of pollutant specific models in completely mixed biological recycle reactors is developed. Pollutant specific Monod constants are developed by considering substrate utilization, cell growth, and endogenous decay rates based solely on influent and effluent specific pollutant concentrations. In this way, models are developed which predict specific pollutant removal in biological reactors. Three nonvolatile compounds are evaluated; namely, phenol, 2,4-dichlorophenol, and 2,4-dinitrophenol and their respective specific Monod constants determined. A pollutant specific model for concurrent biodegradation and volatilization is also developed. A mathematical method for evaluating the pollutant specific Monod constants independent of volatilization kinetics is derived for the volatile compounds dinitrobenzene and carbon tetrachloride. Control strategies are discussed which emphasize the rate limiting pollutant cncept. Conclusions are drawn as to the applicability and limitations of pollutant specific models. (Author's abstract)

KINETIC ANALYSIS OF BOD AND NITROGEN REMOVAL IN AN OXIDATION DITCH,
Kyoto Univ. (Japan). Dept. of Sanitary Engineering.
Y. Terashima, and M. Ishikawa.
Water, Science and Technology, Vol. 17, No. 2/3, p 291-302, 1985. 12 Fig, 4 Tab, 7 Ref.

Descriptors: *Nitrogen removal, *Biochemical oxygen demand, *Oxidation ditch, *Kinetics,

Model studies, Nitrification, Denitrification, Dissolved oxygen, Alkalinity, Computer models, Simulation.

The simultaneous removal of nitrogen as well as organic substances is one of the important characteristics of the oxidation ditch process. To describe this phenomena, synthetic kinetic models including the rates of BOD oxidation, nitrification, denitrification, DO and alkalinity changes, and sludge growth were proposed in this study. Rate equations for these mechanisms were mainly based on Monod type kinetics taking into account several limiting effects among these mechanisms. To develop the design procedure, these kinetic models were combined with the tank-in-series model having circulating and back flows. They were analyzed numerically for typical design and operating conditions. From these computer simulations, successful results to explain these complicated phenomena and several design and operating bases were obtained. (Author's abstract)

STEADY STATE MEASUREMENT OF OXYGENATION CAPACITY,
Amsterdam Public Works (Netherlands). Sewerage and Drainage Dept.
K. de Korte, and P. Smits.
Water, Science and Technology, Vol. 17, No. 2/3, p 303-311, 1985. 9 Fig, 1 Ref.

Descriptors: *Oxygenation capacity, *Steady state measurement, Activated sludge, Aeration, Oxygen saturation, Wastewater treatment.

Oxygenation capacity (OC) measurement by the non-steady state method (reaeration) in tapwater or in activated sludge is difficult and expensive. The steady state method for measuring OC using activated sludge is presented. OC measurement at steady state conditions with (endogenous) activated sludge is practicable for various aeration systems and results in values representative for the practical conditions during measurement. The alpha factor, which influences the oxygen transfer coefficient, depends on the waste characteristics and the type of aeration system. Because the waste characteristics change during treatment, the alpha factor is not constant. With increasing degree of treatment, the influence of the alpha factor decreases. The beta factor, which influence the oxygen saturation, depends on the dissolved solids. In most cases the oxygen saturation is hardly influenced and the oxygen saturation in activated sludge is practically the same as in pure water. Steady state OC measurement is easy to do, is not labor-intensive and consequently can be performed at low cost. The results are satisfactory for most purposes. (Moore-IVI)

REMOVAL OF IRON CYANIDE FROM GOLD MILL EFFLUENTS BY ION EXCHANGE,
Environmental Protection Service, Burlington (Ontario). Waste Water Technology Centre.
D. T. Vachon.
Water, Science and Technology, Vol. 17, No. 2/3, p 313-324, 1985. 6 Fig, 5 Tab, 8 Ref.

Descriptors: *Iron cyanide, *Gold mill wastes, *Ion exchange, Industrial wastewater, Cyanides, Iron compounds, Mine wastes, Resins, Regeneration.

Using a strongly basic anion exchanger (Rohm and Haas Amberlite IRA-958) laboratory ion exchange tests were conducted on the removal of iron cyanide from synthetic and actual gold mill effluents. Variables examined included the effects of pH, concentration and hydraulic loading of the feed on the resin exchange capacity and resin column utilization. The results showed ion exchange to be an effective method of removing iron cyanide to concentrations of less than 3 mg/L. Tests with synthetic gold mill effluents gave resin exchange capacities ranging from 13 to 34 mg CNFe/mL resin depending on the concentration of iron, copper and zinc cyanides in these solutions. When raw barren bleed was tested, an exchange capacity for the ferro/ferricyanides was determined to be about 6 to 8 mg CNFe/mL resin. For chlorinated barren bleed, a resin exchange capacity of 14 mg CNFe/mL resin was observed. A capacity of 19 mg CNFe/mL resin was achieved for tailings pond decant. Regeneration with 15% NaCl provided mixed results with recoveries ranging from 40 to 100% of the iron cyanide exchanged by the resin. Upon multiple exchange-regeneration cycles, the resin lost 25% of the exchange capacity for total cyanide during the first cycle. Subsequently, the loss in exchange capacity was approximately 1% per cycle. Pilot scale tests were considered essential prior to full scale system design. (Author's abstract)

TOTAL EFFLUENT TREATMENT AND RINSE WATER RECLAMATION IN A SEMICONDUCTOR DEVICE MANUFACTURING FACILITY,
C3 International, Minneapolis, MN.
P. S. Cartwright.
Water, Science and Technology, Vol. 17, No. 2/3, p 325-336, 1985. 2 Fig.

Descriptors: *Metal-finishing wastes, *Semiconductor industry, *Wastewater renovation, Water reuse, Wastewater treatment, Electroplating, Copper, Nickel, Ultrapure water, Industrial wastewater.

A manufacturer of semiconductor devices uses several electroplated coatings during the production process. After each plating bath, the devices are rinsed in ultrapure water. Three of the baths contain toxic heavy metals (copper and nickel). In order to minimize the volumetric discharge containing the metals as well as the costs of purifying large quantities of raw water, a complete reclamation and waste treatment system was installed. The system consists of the rinse water reclamation system, the make-up water system, the polishing system, and the waste treatment system. Over 90% of the rinse water is purified back to 18 megohm/cm quality of reuse, and the concentrated toxic chemicals are precipitated and disposed of as an insoluble sludge. Based on maximum rinse water flow of 72,000 gallons per day, the total operating cost is $251.41/day. (Moore-IVI)

DEVELOPMENT OF A NEW PROCESS FOR TREATING URANIUM MINING EFFLUENTS,
Alberta Univ., Edmonton. Dept. of Civil Engineering.
P. M. Huck, W. B. Anderson, and R. C. Andrews.
Water, Science and Technology, Vol. 17, No. 2/3, p 337-350, 1985. 3 Fig, 9 Tab, 7 Ref.

Descriptors: *Uranium mines, *Mine wastes, *Radium, *Coprecipitation, Wastewater treatment, Fluidized bed process, Barium sulfate, Radium sulfate, Radioactive wastes.

Decants from Canadian uranium mining tailings areas are treated to remove radium-226 prior to discharge into the environment. This paper describes the development of a new treatment process for these effluents. This new process differs from existing systems in that it involves the use of a fluidized bed to facilitate (Ba,Ra)SO4 coprecipitation on a granular medium of high surface area. No solids separation step is required, as the granular material is free draining. The new process has been demonstrated to provide radium-226 removal efficiencies consistently exceeding 90% in contact times of about 20 seconds. These short times are in contrast to times on the order of days for conventional pond systems or hours for mechanical systems involving stirred tank precipitation reactors. (Author's abstract)

A study on the biological treatment of coke plant liquid wastes, with high concentration of ammonium nitrogen and phenols, is presented. The anoxic-aerobic single sludge process is used, with the phenols as electron donors in the denitrification process; the inhibiting effect of toxic substances present in the wastewater is prevented by means of dilution. Tests were conducted in a laboratory scale plant to determine the minimum dilution ratio necessary to avoid inhibition and the parameters required for the designing of a full scale plant. Finally the basic design considerations of a wastewater treatment plant for a 1000 t/d coke plant are reported and capital and running costs are evaluated. (Author's abstract)

UV INACTIVATION OF PATHOGENIC AND INDICATOR MICROORGANISMS,
North Carolina Univ. at Chapel Hill. Dept. of Environmental Sciences and Engineering.
J. C. H. Chang, S. F. Ossoff, D. C. Lobe, M. H. Dorfman, and C. M. Dumais.
Applied and Environmental Microbiology, Vol. 49, No. 6, p 1361-1365, June, 1985. 4 Fig, 31 Ref. EPA grant R809593010.

Descriptors: *Ultraviolet radiation, *Disinfection, *Pathogens, *Bioindicators, Bacteria, Viruses, Protozoans, Coliforms, Microorganisms, Spores, Cysts, Wastewater treatment, Water treatment.

Survival was measured as a function of the dose of germicidal UV light for the bacteria Escherichia coli, Salmonella typhi, Shigella sonnei, Streptococcus faecalis, Staphylococcus aureus, and Bacillus subtilis spores, the enteric viruses poliovirus type 1 and simian rotavirus SA11, the cysts of the protozoan Acanthamoeba castellanii, as well as for total coliforms and standard plate count microorganisms from secondary effluent. The doses of UV light necessary for a 99.9% inactivation of the cultured vegetative bacteria, total coliforms, and standard plate count microorganisms were comparable. However, the viruses, the bacterial spores, and the amoebic cysts required about 3 to 4 times, 9 times, and 15 times, respectively, the dose required for E. coli. These ratios covered a narrower relative dose range than that previously reported for chlorine disinfection of E. coli, viruses, spores, and cysts. (Author's abstract)

METHANOGENESIS IN AN UPFLOW ANAEROBIC SLUDGE BLANKET REACTOR AT PH 6 ON AN ACETATE-PROPIONATE MIXTURE,
Agricultural Univ., Wageningen (Netherlands). Dept. of Water Pollution Control.
E. ten Brummeler, L. W. Hulshoff Pol, J. Dolfing, G. Lettinga, and A. J. B. Zehnder.
Applied and Environmental Microbiology, Vol. 49, No. 6, p 1472-1477, June, 1985. 9 Fig, 2 Tab, 24 Ref.

Descriptors: *Methanogenesis, *Upflow anaerobic sludge blanket process, Anaerobic digestion, Biological wastewater treatment, Methanothrix, Methanosarcina, Sludge, Hydrogen ion concentration.

High-rate anaerobic digestion can be applied in upflow anaerobic sludge blanket reactors for the treatment of various wastewaters. In upflow anaerobic sludge blanket reactors, sludge retention time is increased by a natural immobilization mechanism (viz. the formation of granular type of sludge). When this sludge is cultivated on acid-containing wastewater, the granules mainly consist of an acetoclastic methanogen resembling Methanothrix soehngenii. This organism grows either in rods or in long filaments. Attempts to cultivate a stable sludge consisting predominantly of Methanosarcina sp. on an acetate-propionate mixture as substrate by lowering the pH from 7.5 during the start-up to approximately 6 failed. After 140 days of continuous operation of the reactor a filamentous organism resembling Methanothrix soehngenii prevailed in the sludge. The specific methanogenic activity of this sludge on acetate-propionate was optimal at pH 6.6 to 6.8 and 7.0 to 7.2, respectively. (Author's abstract)

SEWAGE EFFLUENT PUMPS,
Texas Agricultural Experiment Station, College Station.
B. L. Carlile.
Southwest and Texas Water Works Journal, Vol. 67, No. 2, p 10 and 12, May, 1985. 1 Fig.

Descriptors: *Low pressure pipe septic systems, *Pumps, *Septic tanks, Soil water, Wastewater irrigation, Mound waste systems, Wastewater disposal.

The low pressure pipe (LPP) septic system provides the greatest promise in home waste disposal because it has demonstrated a remarkable ability to work successfully in the marginal to poor soils that predominate in today's suburban developments. The LPP is a pressure-dosed soil absorption system composed of seven basic elements: (1) septic tank, (2) pumping tank, (3) submersible sewage effluent pump and controls, (4) high-water alarm, (5) supply line and manifold, (6) distribution network, and (7) suitable soil area. Effluent is forced uniformly through holes in a network of drill-perforated polyvinyl chloride pipe, with 1/8-1/4 inch holes spaced 3 to 8 ft apart. The greatest future for sewage effluent pump systems appears to be in small community and cluster housing systems, an application in which it has already gained some acceptance from the Environmental Protection Agency and lending institutions. Other applications of sewage effluent pumps are found in mound waste systems and wastewater irrigation systems. (Rochester-IVI)

ANOMALIES ARISING FROM ARBITRARY MEASURES OF THE STRENGTH OF SEWAGE,
T. Stones.
Effluent and Water Treatment Journal, Vol. 25, No. 3, p 103-107, March, 1985. 8 Tab, 16 Ref.

Descriptors: *Wastewater, *Physicochemical characteristics, *Oxygen demand, Biochemical oxygen demand, Permanganate value, McGowan strength, Chemical oxygen demand, Nitrogenous oxygen demand, Total oxygen demand, Chemical characteristics, Effluent charges.

Characteristics of biochemical oxygen demand (BOD), permanganate value (PV), McGowan strength, chemical oxygen demand (COD), nitrogenous oxygen demand (NOD), and total oxygen demand (TOD) as measures of the strength of sewage were compared. Comparisons of BOD and PV of sewage with the COD have shown that the proportion of the total carbonaceous oxygen demand that they represent varies with the qualitative composition of the sewage. As a result, neither of these arbitrary parameters provides truly comparative measures of the total carbonaceous oxygen demand. They also fail to account for the NOD placed on a treatment plant or, in the case of highly nitrified effluents, the degree of nitrogenous oxidation that has been effected during treatment. Use of these arbitrary measures of sewage strength causes problems in plant management and in proper assessment of trade effluent charges. The BOD and PV measures give results that, in trade effluent charge situations, would cause the industry to be undercharged for treatment if BOD were used, and overcharged if PV were used. The ratio of BOD to COD does, however, give a rational indication of the amenability of sewage to treatment. TOD affords a valid overall criterion for realistic assessment of the capacity and performance of sewage treatment plants, and it provides a means of differentiating between the changes that have been effected in the carbonaceous and nitrogenous oxygen demands during treatment. TOD provides an equitable basis for levying trade effluent charges. (Rochester-IVI)

LUMPED-PARAMETER MODELING OF MULTICOMPONENT ADSORPTION IN THE TREATMENT OF COAL-CONVERSION WASTEWATER BY GAC,
Michigan Univ., Ann Arbor.

D. D. Endicott, and W. J. Weber, Jr.
Environmental Progress, Vol. 4, No. 2, p 105-111, May, 1985. 11 Fig, 8 Tab, 10 Ref.

Descriptors: *Adsorption, *Granular activated carbon, *Coal-conversion wastewater, *Lumped parameter value, *Wastewater treatment, Industrial wastewater, Model studies, Phenols, Cresol, Nitrophenol, Chlorophenol, Total organic carbon.

Granular activated carbon (GAC) adsorption of synthetic, multicomponent coal conversion wastewater was modeled as a lumped parameter using a single component version of the two resistance model (MADAM: Michigan Adsorption Design and Applications Model). The predictive ability of this system was quite good. Synthetic coal conversion wastewaters consisted of different concentrations of phenol, p-cresol, o-nitrophenol, and p-chlorophenol; total organic carbon, the lumped parameter measure, was 932 mg/l in 3 solutions, 646 mg/l in the other two. Values of the standard deviation between model prediction and independent GAC column verification ranged from 3.2 to 17%. Completely mixed batch reactor isotherm and short bed adsorber (SBA) experiments produced adequate adsorption parameters for lumped parameter modeling. The values of the film transfer coefficient obtained by the SBA technique were significantly smaller than those calculated by a correlation procedure. The values of intraparticle surface diffusion coefficient were fairly consistent with reported values of this coefficient for the primary wastewater component phenol. Verification of the model predictions with deep bed adsorber breakthrough data confirmed the validity of the modeling technique for this system. Isotherm parameters had a large influence upon the accuracy of model predictions. The categorization of wastewater solutions based on multicomponent diversity aided in the selection of optimal isotherm parameters for a given DBA prediction. The accuracy of MADAM in modeling the adsorption of synthetic coal conversion wastewater appears sufficient to warrant its use for preliminary design of GAC treatment systems for this application. REMOVAL OF PHOSPHATE AT SEWAGE TREATMENT WORKS AND IMPLICATIONS ON PHOSPHATE LOADINGS INTO LOUGH NEAGH,
Department of Economic Development, Lisburn (Northern Ireland). Water Quality Branch.
A. V. Gray.
Journal of the Institution of Water Engineers and Scientists, Vol. 39, No. 2, p 137-154, April, 1985. 14 Fig, 3 Tab, 13 Ref.

Descriptors: *Phosphorus removal, *Wastewater treatment, *Lough Neagh, *Ireland, Ferrric aluminum sulfate, Phosphorus loading, Algal growth, Costs.

Installation of ferric aluminum sulfate (FAS) liquor dosing for phosphorus removal at 10 sewage treatment works (STW) around Lough Neagh (Northern Ireland) resulted in a reduction of annual phosphorus loading from the STWs from 118 tonnes to 22 tonnes, a change which is estimated to significantly reduce algal growth in the Lough within 5-6 yr. The FAS coagulant was produced by mixing sulfuric acid with ferruginous bauxite mined locally. Laboratory evaluation of the FAS coagulation method showed when good phosphorus removals were achieved, there were correspondingly small metal residuals, suggesting no potential for a metal build-up problem. In addition, biochemical oxygen demand (BOD) reductions were increased by FAS dosing. At the Bullays Hill STW, a trickling filter plant receiving variable strength sewage, an extra 31-40% BOD reduction was obtained in the primary stage due to FAS dosing, suggesting that the method might be an effective means of obtaining a better quality final effluent at less cost than extending the STW in the conventional manner. All plants were ultimately set up for FAS dosing, and successfully achieved the target level of less than 1 mg/l P in the effluent. Isolated instances of pulses of high-P waste disrupted some operations, however. The daily FAS requirement for one plant receiving 10,900 cu m/day was 2,670 l, which at the time cost 92 pounds sterling. The overall volumetric increase in sludge as a result of the FAS dosing procedure was anticipated to be about 50%. (Rochester-IVI)

SURVEY TIES NEEDS TO WATER QUALITY,
A. B. Nichols.
Journal of the Water Pollution Control Federation, Vol. 57, No. 5, p 355-357, May, 1985. 2 Tab.

Descriptors: *Wastewater treatment, *Costs, *Water quality control, Population dynamics, Pollution load, Water pollution.

According to the 1984 U.S. Environmental Protection Agency (EPA) Needs Survey Report to Congress, $85 billion would be required to meet the wastewater treatment needs of the 1984 population of the United States and its territories, $101.7 billion to meet eligible year 2000 needs, and $108.9 billion to meet total (unrestricted) needs for the year 2000. Areas with relatively high needs for publicly owned wastewater treatment to the year 2000 include California (6,313 million), Florida ($4,533 million), Illinois ($4,204 million), Massachusetts (4,696 million), New Jersey ($4,684 million), New York ($15,184 million), Ohio ($ 4,834 million), Pennsylvania ($4,749 million), and Texas ($4,145 million). When 1984 needs are met, an estimated 32% more people (approximately 70 million) will receive treatment services, and pollutant load will drop 34%, resulting in improved water quality in streams throughout the country. The service population is estimated to increase by 55% by the year 2000 and the aggregate effluent load is estimated to increase 9%. The increase in pollutant removal capacity at municipal facilities probably will not keep pace with increased population growth. As a result, if year 2000 needs are met, water quality in the nation overall will remain about the same as today, but if the year 2000 needs are not met, severe water quality degradation will result. State planning has not been sufficient to fully address the impact of future pollutant loads resulting from bringing treatment services to more people. (Rochester-IVI)

Descriptors: *Wastewater treatment facilities, *Costs, Water management, Wastewater lagoons, Effluents, Ammonia, Water rights, Irrigation water, Trout streams, Water quality standards.

A four-cell lagoon system was designed and constructed to serve the town of Buffalo, Wyoming (population about 5,000). Reassessment of ammonia discharge criteria using a predictive model was the key to meeting stream criteria while resolving water rights issues and lowering charges. Discharge from the treatment plant to Clear Creek, a trout stream, occurs only from October through April of each year, with discharge into irrigation ditches during the rest of each year. Chlorination is employed only when discharging to irrigation ditches. The primary cells, which operate in parallel, are aerated to maximize treatment, prevent ice formation during winter, and minimize odors. All lagoons are lined with a bentonite-soil mixture to protect underlying groundwater. Gravity inflow to the primary cell eliminates the need for a raw wastewater pumping station, but pumping up through the polishing cells is required to conform to site topography. Implementation of this water management plan resulted in a present-worth saving of $4 million compared to an oxidation ditch system, the only acceptable conventional alternative in Wyoming. E. Arvin.
CRC Critical Reviews in Environmental Control, Vol. 15, No. 1, p 25-64. 13 Fig, 15 Tab, 102 Ref.

Descriptors: *Biological treatment, *Phosphorus removal, *Wastewater treatment, Water treatment, Nitrates, Anaerobic digestion, Sludge digestion.

Principles of the main treatment processes for removal of P from wastewater, the mechanism of biological P removal, chemical phosphate precipitation in biological P-removal systems, characterization of P fractions in sludge, factors in design of mainstream and sidestream treatment plants, and operational problems of these plants are reviewed. Sidestream processes are able to reduce P to a level of about 1 mg of P per liter under optimal conditions; mainstream processes, under optimal conditions, can reduce P to about 2 mg/l, which, with a small dosage of iron or aluminum salt, can be further reduced to 1 mg/l. Both sidestream and mainstream processes may require effluent filtration if the effluent P concentration must comply with stringent limits. This is due to the relatively high P content in the sludge, about 4% of P in sidestream process and 3.5-6% in mainstream processes. The extent of biological P removal from wastewater increases with increasing concentrations of soluble, readily biodegradable organics in the sewage. Nitrate and oxygen in the influent to the anaerobic reactor decrease biological P removal through oxidation of the soluble, readily biodegradable organic matter. The reactor design in biological P-removal plants is normally based on simple criteria like (aerobic) sludge age and detention times. Future design will most likely be based on process models that take into consideration the specific composition of the wastewater. New models emphasize the role of poly-P-accumulating bacteria. ACTIVATED BIOFILTER PROCESS FOR WASTEWATER TREATMENT,
Regina Univ. (Saskatchewan). Faculty of Engineering.
T. Viraraghavan, R. C. Landine, E. L. Winchester, and G. P. Wasson.
Effluent and Water Treatment Journal, Vol. 25, No. 4, p 129-134, April, 1985. 1 Fig, 6 Tab, 15 Ref.

Descriptors: *Wastewater treatment, *Activated biofilters, *Trickling filters, *Activated sludge process, *Biofilters, Filters, Water treatment, Cold regions, Costs, Economic aspects, Secondary wastewater treatment.

The activated biofilter (ABF) process is a hybrid of attached (trickling filter) and suspended (activated sludge) growth systems. For most domestic wastes the biocell is typically designed at a biochemical oxygen demand (BOD) loading of 3.2 kg/cu m per day. The settleability of the mixed liquor obtained from the biocell tower is quite good, even under severe shock loading. Numerous pilot studies have been conducted by the manufacturer and a case study was conducted by the US Environmental Protection Agenvcy at Helena, Montana. ABF was evaluated along with other processes for employment at Millidgeville, Saint John, New Brunswick, Canada, where a capacity of 6,820 cu m/day was anticipated based on service to a population of 12,000. Total present value costs for the competing systems were as follows: modified activated sludge process, $6,647,000; ABF, $6,023,000; rotating biological contactor system, $5,990,000; and deep shaft process, $7,431,000 (base design) or $7,625,000 (optimal design). Based on the economic criteria, plus energy, site, operational, and other considerations, ABF was recommended for secondary treatment at Millidgeville. The ABF system confers operational stability inherent in a trickling-filter system. Employment of short-term aeration as part of the process improves reliability. Heat loss across the system is minimal, an advantage in cold-climate operation. (Rochester-IVI)

PERFORMANCE OF AN UPFLOW ANAEROBIC REACTOR COMBINING A SLUDGE BLANKET AND A FILTER TREATING SUGAR WASTE,
National Research Council of Canada, Ottawa (Ontario). Div. of Biological Sciences.
S. R. Guiot, and L. van den Berg.
Biotechnology and Bioengineering, Vol. 27, No. 6, p 800-806, June, 1985. 12 Fig, 4 Tab, 11 Ref.

Descriptors: *Upflow blanket filters, *Anaerobic digestion, *Biomass, Upflow reactors, Wastewater treatment, Biological wastewater treatment, Industrial wastewater, Food processing industry, Sugars.

The loading capacities of an anaerobic wastewater treatment system are essentially dictated by the amount of active biomass that can be retained in the reactor, provided a sufficient contact between active biomass and waste organic can be assured. A new hybrid reactor, the upflow blanket filter (UBF), combines an open volume in the bottom two-thirds of the reactor for a sludge blanket and submerged plastic rings in the upper one-third of the reactor volume. This UBF reactor was operated at 27 C at loading rates varying from 5 to 51 g COD/L d with soluble sugar wastewater (2500 mg COD/L). Maximum removal rates of 34 g COD/L d and CH4 production rates of 7 vol/vol d were obtained. The biomass activity was about 1.2 g COD/g volatile suspended solids per day. Conversion (based on effluent soluble COD) was over 93% with loading rates up to 26 g COD/L d. At higher loading rates conversion decreased rapidly. The packing was very efficient in retaining biomass. The filter at the top of the UBF reactor has two advantages: space occupied by packing is not lost space for active biomass; and exploiting the floating capacity of the plastic rings is an inexpensive method to enhance biomass accumulation. The system should be cheaper than an anaerobic filter (less packing) and more likely to avoid the problems of channeling and plugging usually occurring in the bottom part of an anaerobic filter. ANAEROBIC PRETREATMENT REDUCES MILL COSTS, IMPROVES EFFLUENT QUALITY,
Buhrmann-Tetterode N.V., Roermond (Netherlands). Wastewater Dept.
L. H. A. Habets, and J. H. Knelissen.
Pulp and Paper, Vol. 59, No. 4, p 66-69, April, 1985. 2 Fig, 2 Tab, 2 Ref.

Descriptors: *Wastewater treatment, *Pulp and paper industry, *Industrial wastewater, *Anaerobic digestion, Biogas, Costs, Water treatment.

The Upflow Anaerobic Sludge Blanket (UASB) reactor has proven to be efficient and cost effective with paper mill waste of high organic content in several different installations in the Netherlands. Pilot studies of the UASB process were conducted at various different scales, and full-scale reactors are now operating at Oude Pekala (2,472 cu ft volume), Roermond (35,300 cu ft volume), and Celtona (24,700 cu ft volume). The UASB process will function with either granular or non-granular sludge; granular sludge permits higher loadings without loss of sludge in the effluent. At the Roermond plant, where the USAB reactor pretreats wastewater to reduce the loading of an activated sludge (aerobic) plant, a daily loading of 0.99 lb chemical oxygen demand (COD)/cu ft/day has been achieved without problems. COD removal has stabilized at 75% or better, and biochemical oxygen demand (BOD) removal is almost 90%. The reactor also produces 4,590 cu ft/hr of biogas containing 1-3% H2S, which is used to generate steam used in paper production. Each ton of COD removal yields 4.7 tons of 150 psi steam; excess

biogas is flared. Each pound of COD converted yields 0.1 lb of new granular sludge, which can be used to start up new USAB reactors. After more than a year of operation, the Roermond anaerobic treatment plant has proven to be more cost-effective than aerobic digestion, mainly because the quantity of energy in the biogas produced exceeds the energy consumed to power the process. ION EXCHANGE POTENTIALLY EFFECTIVE IN REDUCING EFFLUENT FROM BLEACH PLANT,
Jordan (Edward C.) Co., Inc., Portland, ME.
J. H. Fitch, Jr.
Pulp and Paper, Vol. 59, No. 4, p 132-135, April, 1985. 1 Fig, 3 Tab.

Descriptors: *Ion exchange, *Bleaching wastes, *Industrial wastewater, *Pulp and paper industry, *Wastewater treatment, Resins, Zinc, Copper, Cadmium, Nickel, Metals.

Batch and pilot scale ion exchange resin treatment plants at the bleach plant at Billerud Uddeholm (Skoghall, Sweden) effectively remove color, chemical oxygen demand, chlorinated phenols, chlorinated guaiacols, and complexed metals. The treatment plants, which use a special resin supplied by Diamond Shamrock Corporation, do not remove resin, fatty acids, and phthalates. Inorganic chloride was removed initially, but the removal rate declined after the cycle started. Zinc and copper are removed through complexation and chelation. Cadmium and nickel appear to be removed effectively in the second column but are virtually untouched in the first. Chlorinated phenols and guaicols are removed more efficiently toward the end of the treatment cycle, probably because of loss of ionic character at low pH and the subsequent interaction with compounds previously removed. Extended contact time yielded no benefits; effective removal was lost rapidly, and a considerable number of pollutants passed through the columns. Although the startup period was long and troublesome, a full-scale treatment plant has been operating for almost 4 yr with high availability and without any real problems. The resin life (estimated at 6 mo) is shorter than it should be, which has increased operating costs of the plant because chemical costs increase as the resin ages. (Rochester-IVI)

ANAEROBIC WASTEWATER TREATMENT SYSTEM OPERATES AT VERY LOW COST,
Tampella Oy A.B., Tampere (Finland).
S. Rekunen.
Pulp and Paper, Vol. 59, No. 5, p 122-125, May 1985. 3 Fig, 3 Tab, 3 Ref.

Descriptors: *Pulp and paper industry, *Anaerobic digestion, *Industrial wastewater, Methane, Biogas, Operating costs, Costs, Activated sludge process.

The first stage of a methane-producing anaerobic reactor treatment system has begun operating at the Tampella paper mill at Anjala, Finland. This plant treats one third of the mill's total wastewater using reactors of 106,000 cu ft total volume; wastewater from the debarking plant, paper machines, and groundwood production is treated. The second stage of the plant will accomodate the rest of the total of 31 tons/day of biochemical oxygen demand (7-day) and 22 tons/day of suspended solids from the mill to achieve the regulatory goals of 6.6 tpd BOD and 8.8 tpd suspended solids. The process used was developed in the laboratory and in pilot studies conducted at the Anjala plant; it is named the TAMAN process. From the preclarifier, wastewater goes to the acid fermentation facility where micoorganisms break down organic matter to low-molecular-weight acids. In the acid stage, the homogenized wastewater is conducted to the methane stage, where bacteria break down the organic acids to methane and carbon dioxide. Some 4.8 cu ft of biogas is formed per pound of BOD reduction; it contains about 70% methane by volume. The pH of the wastewater is adjusted with Ca(OH)2 and nutrients such as urea and phosphoric acids can be added, if necessary. Sludge is collected in a separate tank from which it is conducted to a mechanical sludge processor. Sludge then can be burned in a fluidized bed boiler. Biogas is burned in a boiler or flared. For the Anjala site, the TAMAN process had construction costs similar to the activated sludge process, but the TAMAN process operating costs were only 10% of those for the same treatment capacity of activated sludge. In addition, the fuel value of the biogas is nearly $145,000 (US) per year. (Rochester-IVI)

ENCLOSED VESSEL COMPOSTING BEGINS AT CAPE MAY COUNTY,
Cape May County (NJ) Municipal Utilities Authority.
W. W. Cathcart.
BioCycle, Vol. 26, No. 4, p 24-27, May-June, 1985. 5 Fig, 3 Tab.

Descriptors: *Composting, *Cape May County, *New Jersey, *Enclosed vessel composting, Sludge utilization, Costs, Wastewater treatment.

The composting system for treatment of domestic sewage sludge in Cape May County, New Jersey is described. The ABV/Purac system of in/vessel composting can be described as a vertical plug flow process. The composting vessel is fed from above by a spreader conveyer with material to be composted, and the composted material is discharged from the bottom by a power screw conveyor. Air is supplied at the bottom of the reactor and exhausted at the top. A General Electric Series Six programmable control handles the process control elements of the system. Temperature, carbon dioxide, status of the conveying system, status of the aeration system, weight of the input material, weight of the transferred material, weight of the output compost, and various warning alarms are continuously monitored. The facility includes a sludge container building, amendment storage building, operations building, maintenance building, BIO reactor, blower room, CURE reactor, and compost storage building. The development and construction costs were $9.1 million (US) and annual operating costs are $575,000. Dewatered municipal sludge of minimum 20% total sludge solids and sludge cake density of 50-60 pounds/cu ft is the input; output is a medium coarse to fine, friable compost of 10 mm maximum organic particle size and 60% maximum moisture. Volatile solids are reduced a minimum of 40% by the facility, which processes 12.1 tons per day in summer (tourist season) and 2.2 tons/day (off-season) when operating continuously. It is anticipated that some operating costs will be offset by revenues generated from sale of finished compost and by user fees charged for disposal of sludge. (Rochester-IVI)

Descriptors: *Public health, *Developing countries, *Sanitation, *Drinking water, Water supply, Water quality, Bacteria, Protozoa, Viruses.

Most of the diseases associated with inadequate water supplies and sanitation in developing countries are caused by bacteria, protozoa, viruses or worms. The contamination of water by chemicals is a less common factor. The prevention of any infectious disease requires the transmission cycle to be interrupted. Water and sanitation related diseases may have either complex or alternative transmission cycles. In complex transmission cycles, a period of development occurs in one or two specific intermediate hosts before the pathogen becomes infective to humans. Health considerations in project appraisal which are considered include community heath status, existing water supply, proposed water supply, existing sanitation, proposed sanitation, community health programs and staff, community perception of needs, community population characteristics, community education facilities, project communication support, media for health education in the community, community organization and resources, community development projects, and a national support system. Descriptors: *Water treatment, *Enzymes, *Aromatic compounds, Phenols, Chlorinated phenols, Peroxidase-peroxide system, Monochlorophenol, Dichlorophenol, Pentachlorophenol.

The removal of aromatic compounds by the peroxidase - hydrogen peroxide system was studied at low levels which might be encountered in surface waters which receive some industrial discharge. Three compounds, mono-, di-, and pentachlorophenol, are used as model aromatic compounds. The treatment process is characterized both in terms of specific compound removal and removal of its reaction products. The enzyme system is effective in eliminating chlorinated phenols at low levels from drinking water supplies, but does not remove their products from the water. Further work is necessary to determine if these by-products present a potential risk for the human health and if they are removed in other unit processes. The enzymatic procedure may offer an alternative to the standard treatments, for example for sporadic taste and odor problems associated with chlorinated phenols. (Moore-IVI)

Descriptors: *Drinking water, *Water treatment, *Viruses, *Bacteria, Bioindicators, Disinfection, Enteroviruses, Raw water, Coliform, Chlorination, Sedimentation, Filtration, Ozonation.

Seven drinking water treatment plants were sampled twice a month for 12 months to evaluate the removal of indicator bacteria and cytopathogenic enteric viruses. Samples were obtained at each level of treatment: raw water, postchlorination, postsedimentation, postfiltration, postozonation, and finished (tap) water. Raw water quality was usually poor, with total coliform counts exceeding 105 to 106 CFU/liter and the average virus count in raw water of 3.3 most probable number of cytopathogenic units (MPNCU)/liter; several samples contained more than 100 MPNCU/liter. All plants distributed finished water that was essentially free of indicator bacteria as judged by analysis of 1 liter for total coliforms, fecal coliforms, fecal streptococci, coagulase-positive staphylococci, and Pseudomonas aeruginosa. The total plate counts at 20 and 35 C were also evaluated as a measure of the total microbial population and were usually very low. Viruses were detected in 7% (11 of 155) of the finished water samples (1,000 liters) at an average density of 0.0006 MPNCU/liter the highest virus density measured being 0.02 MPNCU/liter. The average cumulative virus reduction was 95.15% after sedimentation and 99.97% after filtration and did not significantly decrease after ozonation or final chlorination. The viruses isolated from treated waters were all enteroviruses: poliovirus types 1, 2, and 3, coxsackievirus types B3, B4, and B5 echovirus type 7, and untyped picornaviruses. (Author's abstract)

ASSESSMENT OF WATER UTILITY INFORMATION SYSTEMS AND THEIR USE OF COMPUTERS,
Cincinnati Univ., OH. Dept. of Mechanical and Industrial Engineering.
R. L. Shell, and N. A. Damachi.
Water Resources Bulletin, Vol. 21, No. 2, p 323-330, April, 1985. 1 Fig, 9 Tab, 9 Ref.

Descriptors: *Utilities, *Water conveyance, *Water treatment, *Computers, Ohio, Indiana, Kentucky, Recordkeeping, Maintenance, Inspection, Water storage, Water loss, Water metering.

A direct mail survey of all water utilities serving populations of 2,000 or more in the tri-state area - Ohio, Indiana, and Kentucky was conducted, and the following were determined: utility profile information, e.g., public/private ownership, age, number of accounts, etc.; an assessment of the degree of computerization presently in place to perform various functions; and an assessment of any plans that the utilities may have for future computerization. To analyze the data, an index of computerization was defined as the number of departments or major areas of each utility that presently have some computerization. Departments and major areas included: water pumping, treatment, storage and distribution; metering and billing; accounting and personnel records; inspection and maintenance; and utility operations. Discriminant analysis revealed strong significant differences between utilities that plan to use computers and those that do not. There is a rather limited use of computers in the tri-state area. Fifty-one percent of the water utilities in Kentucky do not use computers at all in their operations. In Ohio and Indiana the figures are 39% and 51%. Many utilities use computers only for billing. The major form of recordkeeping in water utilities in the tri-state area is manual. Water loss in many systems appears to be a problem in Kentucky. Enormous potential exists in small and medium sized utilities for computerization to improve operational efficiency. (Moore-IVI)

TRENDS IN DRINKING WATER TREATMENT THE SHAPE OF THINGS TO COME,
Metcalf and Eddy of New York, NY.
G. P. Fulton.
Public Works, Vol. 116, No. 6, p 80-83, 138 and 140, June, 1985.

Descriptors: *Drinking water, *Water treatment, *Future planning, Modernization, Filtration, Organics removal, Disinfection, Chlorination, Measuring instruments, Costs, Manpower.

Treatment systems of the future will be different from older systems as water purveyors use innovative techniques to achieve solutions to particular water quality problems at particular sites. Earlier designs employed a 'worst case' solution, which tended to introduce redundancy of equipment and high cost. Future systems will control intermittent quality problems (eg, giardiasis, viral epidemics, accidental waste spills, leaching from waste dumps, and pesticide contamination) with approaches designed for the conditions at a given locality. The preeminent changes likely to occur in surface water treatment for drinking should be in filtration, organics removal, and disinfection. Both operational and equipment innovations will be employed to improve filtration results. In the interim period before final regulations for organics are established, primary emphasis will probably be on multi-purpose measures that moderate potential organic contamination problems, including aeration or air stripping, air flotation, granulated organic carbon filter media, and ozonation. Accepted disinfection alternatives to conventional chlorination are chloramines, chlorine dioxide, and ozone. Monitoring and control systems are becoming more complicated, with greater reliance on computers for both data recording and operations; the greatest changes will occur in instrumentation. Staffs at treatment plants will become smaller, but more highly trained, as equipment becomes more sophisticated. Future plants wil be customized designs, each intended to cope with particular source water quality features. Use of multi-purpose unit process elements will be more common to both optimize performance and reduce treatment costs. (Rochester-IVI)

UTILITY BATTLES IRON AND MANGANESE,
Hibbing Public Utilities Commission, MN.
R. P. Richards, and S. N. Foellmi.
Public Works, Vol. 116, No. 6, p 91-95, June, 1985. 4 Fig, 1 Tab.

Descriptors: *Water treatment, *Drinking water, *Iron removal, *Manganese removal, *Hibbing, *Minnesota, Pilot plant studies, Water supply, Municipal water, Oxidation, Chlorine, Potassium permanganate.

Computer analysis and a pilot plant study were employed to develop an increased capacity and improved water quality in a supply system deriving all its water from wells. The water-supply system, located in Hibbing, in the heart of the northeastern Minnesota iron mining district, had a history of problems with high iron and manganese (exceeding Environmental Protection Agency (EPA) Secondary standards in flow from all its wells but one). In redesigning the system, four alternatives were examined in which water from the Scranton (high quality water) wells would be pumped to the distribution system, where it would be blended with effluent from a treatment plant that would process the water from the other wells. Chemical oxidation with chlorine and potassium permanganate and continuously regenerated manganese greensand pressure filters was shown through analysis to be the most cost-effective treatment process. A pilot plant test showed that this treatment method could reduce the iron and manganese contents below EPA limits; the pilot test also provided filter loading rate, filter run time, maximum head loss across the filter, and the chemical feed dosage data that were useful in designing the full-scale plant. The water treatment plant was placed on line in early 1984, and the flow rate has averaged 1.9 million gallons/day (mgd), with a peak production of 3.2 mgd. Finished water has consistently met all regulatory agency standards. The pilot plant work provided an excellent projection of the full-scale plant chemical treatment requirements. Treatment cost for iron and manganese removal (chlorine and potassium permanganate) has been about $24/million gallons. (Rochester-IVI)

CITY IMPLEMENTS TRIHALOMETHANE CONTROL PROGRAM,
Neel-Schaffer, Inc., Jackson, MS.
J. G. Sigman, and W. M. Ashley.
Public Works, Vol. 116, No. 6, p 98-99, June, 1985. 1 Fig, 2 Tab.

Descriptors: *Trihalomethanes, *Water treatment, *Jackson, *Mississippi, *Drinking water, Source of pollutants, Chlorination, Water pollution control, Filtration, Sedimentation.

The city of Jackson, Mississippi has successfully initiated an ammoniation program to bring trihalomethane (THM) levels down to meet National Interim Primary Drinking Water Regulations. In 1975, the total THM in water in Jackson was 334 ppb, primarily as a result of increasing urbanization along the banks of the Pearl River upstream from where the treatment plant withdraws source water. A variation to the usual chloramination design that was used here was carrying a free chlorine residual through part of the treatment process, which was done in response to the following local conditions: (1) onsite storage at the plant is limited, with only 6-10 hr between flash mixing and finished water pumping, (2) the Pearl River exhibits great fluctuations in bacterial quality, (3) the 28 rapid sand filters at the plant are exposed, and (4) it was decided to change the disinfection systems from pre- and post- chlorination to mid-point (after sedimentation and before filtration) chlorination and post (just prior to finished water pumping) ammoniation. Pre-start-up monitoring showed that in every quarterly sample from January 1981 through August 1983, the 100-ppb limitation for total THMs was exceeded, with an average typically around 200 ppb, but running to as high as 450 ppb. In the quarters since startup, there has been a 70% reduction in total THMs, with the average quarterly value at six sample points being around 84 ppb. Consumers report that as a result of elimination of the free chlorine residual the water tastes better. (Rochester-IVI)

RE-EVALUATING THE EXTENT OF GROUNDWATER CONTAMINATION,
National Water Well Association, Worthington, OH.
J. H. Lehr.
Water and Pollution Control, Vol. 123, No. 3, p 16-18, May/June, 1985.

Descriptors: *Water management, *Groundwater supply, *Water supply development, *Groundwater pollution, Management, Decision making, Water resources development, Planning, Evaluating.

Through a series of assumptions, it is concluded that, even with groundwater pollution occurring, we have yet to pollute even 1% of the total groundwater supply. The initiation of new sources of groundwater pollution can be eliminated within the next 10 years which will put an end to ill conceived practices that brought about the problem in the first place. The existing contamination plumes will not have moved much further or polluted much more by then than they already have. The odds are that we will end up with 98% of the groundwater still unpolluted by the end of this century. Practices which have led to the path of wanton wastefulness are reviewed. The first course of action should be to implement some management options that will work. Also needed is an evaluation of where a lack of efficiency exists in using water and these practices should be eliminated. An evaluation of inefficient irrigation practices is one step. The conjunctive use of surface and groundwater can help reduce the impact of localized droughts. Perhaps one of the most neglected management options is that of artificial recharge. There is no loss to evaporation as with a surface reservoir and many sources of water, which normally flow out of the watershed, can be recycled and saved right there. (Baker-IVI)

This paper reviews progress on urban stormwater management and pollution control, with emphasis on non- and low-structurally intensive techniques along with the total system approach encompassing control-treatment. Many of the U.S. Environmental Protection Agency's demonstration-evaluation projects are presented to exemplify: Land Management Techniques, i.e., land use planning, best use of natural drainage, dual use of retention and drainage facilities required for flood control designed concurrently or retrofitted for pollution control, porous pavement, surface sanitation, and chemical use control; Collection Systems Control, i.e., catchbasin cleaning, flow regulators (including swirl and helical devices), and the new concepts of elimination or reduction of unauthorized cross-connections, in-channel/conduit storage and/or other forms of storage for bleed-back to existing treatment plants; Storage including in-receiving water storage; Treatment, i.e., physical/chemical, disinfection, and a treatment-control planning and design guidebook; Sludge and Solids Residue from Treatment; and Integrated Systems, i.e, storage/treatment, dual-use wet-weather flow/dry-weather flow facilities, and reuse of stormwater for nonpotable purposes. Recommendations for the future in the areas of: control based on receiving water impacts, toxics characterization and their control, sewer system cross-connections, integrated stormwater management, and institutional/sociological/economic conflicts are also presented. FARMERS' ATTITUDES TOWARD NONPOINT POLLUTION CONTROL AND PARTICIPATION IN COST-SHARE PROGRAMS,
Virginia Polytechnic Inst. and State Univ., Blacksburg. Dept. of Agricultural Economics.
W. R. Kerns, and R. A. Kramer.
Water Resources Bulletin, Vol. 21, No. 2, p 207-215, April, 1985. 6 Tab, 14 Ref.

Descriptors: *Nonpoint pollution sources, *Water pollution control, *Attitudes, *Farms, *Cost sharing, Virginia, Loans, Taxes, Soil loss, Soil erosion, Public participation.

The success of government programs to control nonpoint source pollution depends upon attitudes toward those programs and the availability of technical and financial assistance. Applicants for the Rural Clean Water Program cost-share funding in Virginia possess different personal and operational characteristics than do nonapplicants. Factors associated with participation in the Rural Clean Water Program differed from those associated with the more traditional soil conservation programs. Discriminant analysis was used to differentiate between other farmers who may become applicants and nonapplicants. Farmers' attitudes toward various policy options for inducing implementation of nonpoint source management practices varied greatly. Farmers were most favorable to cost sharing, low-interest loans and tax credits, and least favorable to a soil loss tax. They were either very favorably or very unfavorably inclined toward cross-compliance between pollution control and other agricultural programs. (Author's abstract)

Water Resources Bulletin, Vol. 21, No. 2, p 315-321, April, 1985. 2 Fig, 3 Tab, 10 Ref.

Descriptors: *Water quality management, *Lake restoration, *Johnson Sauk Trail Lake, *Illinois, Eutrophication, Destratification, Algal control, Copper sulfate, Potassium permanganate.

Johnson Sauk Trail Lake (Illinois) remains highly eutrophic, even though the watershed has long been returned to an undisturbed condition with permanent vegetative cover and with little or no land disturbance in the watershed. Internal regeneration of nutrients has been identified as the major source of nutrients to the lake. Lake destratification, selective harvesting and removal of weeds, and control of algal blooms using chelated copper sulfate application followed by potassium permanganate application have all been chosen as management techniques for improving water quality conditions in the lake. These in-lake techniques are considered not as palliative measures, but as necessary tools in enhancing the lake's water quality characteristics. (Author's abstract)

ENVIRONMENTAL PROTECTION IN THE REPUBLIC OF IRELAND,
Trinity Coll., Dublin (Ireland). Environmental Sciences Unit.
N. F. Gray.
Effluent and Water Treatment Journal, Vol. 25, No. 3, p 83-89, March, 1985. 1 Tab, 11 Ref, 2 Append.

Descriptors: *Environmental protection, *Ireland, *Legislation, Protection, Water pollution control, Resources management, Water management.

Water quality maintenance laws and agencies in the Republic of Ireland were evaluated. Unlike many other European countries, no single body is responsible for, or coordinates, the management of water resources. The system is local authority-based, and relies heavily on state and semi-state bodies to carry out a number of important functions. Before the implementation of the Local Government (Water Pollution) Act of 1977, three pieces of legislation, the Public Health Act of 1979, the Fisheries (Consolidation) Act of 1959, and the Local Government (Planning and Development) Acts of 1963 and 1976, were widely used in the protection of waters and public supplies. The Water Pollution Act attempts to centralize the responsibility for water resource management with local authorities, but numerous other organizations still retain various statutory responsibilties in relation to water management and pollution control. The Water Pollution Act obliges local authorities to monitor and analyze discharges and receiving water, but few are able to do so without relying on other agencies for laboratory services. Many other organizations carry on monitoring programs; at present the data are not coordinated, but eventually a catchment area-based data collection system will be instituted by local authorities. The Water Pollution Act was also designed to satisfy the legislative requirements of the European Economic Community directives, which it has successfully done to date. The Water Pollution Act is clearly adequate to protect Ireland's water resources, and overlapping sections of other acts should be repealed to eliminate duplication of responsibilities and legislative confusion. A more coordinated, catchment-based water management system, with complete control of all water functions, would appear to be the most cost-effective way for efficient water resource management, particularly pollution control. INNOVATIVE WATER QUALITY-BASED PERMITTING: A POLICY PERSPECTIVE,
Skylonda Group, Inc., Menlo Park, CA.
D. Downing, and S. Sessions.
Journal of the Water Pollution Control Federation, Vol. 57, No. 5, p 358-365, May, 1985. 22 Ref.

Descriptors: *Permits, *Water quality, Water pollution control, Costs, Nonpoint pollution sources, Water pollution sources, Administration, Environmental effects.

The Water Innovations Project (U.S. Environmental Protection Agency, Office of Policy, Planning, and Evaluation) examined two generic types of permitting innovations: those that make greater use of the capacity of the water body to assimilate wastes, and those that encourage more efficient allocation of a given total wasteload through trading mechanisms. Innovations in the first group are seasonal permits, variable permits, seasonal standard and site-specific standards. Interplant source trades, point/nonpoint source trades, and banking comprise the second group. Cost effects, water quality eligible pollutants, and administrative issues associated with these permitting innovations were studied. All innovations would apply only where controls beyond technology-based standards are required to attain water quality standards. The innovations are most directly applicable to conventional pollutants and nutrients, not for toxics. Based on case analysis the innovations appear to provide large cost savings while protecting water quality. Administrative safeguards, such as criteria for particular pollutants when innovative permitting is used, or restrictions on situations in which innovative permitting can be employed, are needed to protect water quality and program integrity, while avoiding excessive administrative burdens. Analysis of case studies actual experience in states where these innovations are already in use indicated substantial cost savings, few if any adverse environmental effects, and manageable administrative burdens. In some states, innovative permitting broke regulatory impasses and led to earlier attainment of water quality standards than would otherwise have occurred. (Rochester-IVI)

CONTROL OF METAL APPLICATION RATES FROM SEWAGE SLUDGE UTILIZATION IN AGRICULTURE,
Anglian Water Authority, Huntingdon (England). Directorate of Scientific Services.
P. J. Matthews.
CRC Critical Reviews in Environmental Control, Vol. 14, No. 3, p 199-250. 4 Fig, 19 Tab, 166 Ref.

Descriptors: *Sludge disposal, *Metals, *Agriculture, *Environmental protection, Water pollution control, Fertilizers, Heavy metals, Arsenic, Boron, Cadmium, Chromium, Cobalt, Copper, Lead, Manganese, Mercury, Molybdenum, Nickel, Selenium, Zinc, Soil, Economic aspects.

Potentially toxic metals in sewage sludge and their chemistry in the sludge medium, potentially toxic metals in normal and sludged soils, chemical controls on metal availability, and the effect of potentially toxic metals on crops and the agricultural consequences of their presence, are reviewed, and recommendations for controlling the application of sludge to land are presented. Chemical elements of interest in this field are arsenic, boron, cadmium, chromium, cobalt, copper, lead, manganese, mercury, molybdenum, nickel, selenium, and zinc. A survey of sludge disposal in the United Kingdom in 1980-81 showed that disposal of sludge on general arable land and marine dispersal accounted for more than half of the ultimate disposal of sewage sludge. The use of sewage as a fertilizer should be controlled so as to meet the following objectives: (1) avoid spread of human, animal, and plant diseases, (2) avoid public nuisance, particularly odors, (3) avoid harm to crop quality and yield resulting from soil contamination, (4) protect surface and ground waters, and (5) provide an acceptable and useful service to farmers. Application of metals to agricultural land may be controlled by limiting their concentrations in sludge, limiting their concentrations in sludge-amended soils, and limiting the rate of accumulation of metals in soil. Approaches used in deriving guidelines differ according to whether regional soils are acidic or alkaline. Industrial effluent control is an important element of controlling sludge metal concentrations; presence of industrial metals may be a factor in determining whether fertilization is an acceptable use for a particular sludge. At present, costs of removing metals from sewage sludge are prohibitive when compared to the value of the isolated metals. If the prices of metals rise, industrial d may decline, reducing the metal conten sludge, thus making metal recovery fro less, rather than more, economic. (Roche W86-00854

BARRIER TO UPGRADING FUNDING,
Purdue Univ., Lafayette, IN.
R. O. Walker, Jr.
Water Engineering and Management, Vol. 132, No. 5, p 20-28, May, 1985.

Descriptors: *Infrastructure, *Public policy, *Funding, Policy making, Decision making, Urban planning, Costs, Economic aspects, Cost allocation.

An August, 1984, workshop on 'Technical Alternatives for Urban Infrastructure' brought out several aspects of the infrastructure problem as faced by American cities. The problems of infrastructure are not merely physical, or engineering, problems, but have social, economic, community government, and regulatory aspects. Major social and economic changes, such as the change from an industrial to a service economy, mean that the demands made on the infrastructure are changing. The problem is not merely one of upgrading or repairing existing facilities, but of simultaneously adapting them to changing needs of the users. Funding for major projects is the greatest obstacle to infrastructure improvement now that federal support is being withdrawn. Aside from federal programs, funding methods that have been used include (1) revenue bonds, (2) New Jersey's infrastructure bank, from which local communities may borrow funds at low or no interest, (3) developer exactions, and (4) 'privatization' of the infrastructure. A coalition of all segments forming the framework of the urban infrastructure system and its users should be the source of the information required for the decision-making process. New methods of financing, marketing, and adoption of new technologies must be encouraged and supported. (Rochester-IVI)

OVERCOMING THE BARRIERS,
East Bay Municipal Utility District, Oakland, CA.
J. B. Gilbert.
Water Engineering and Management, Vol. 132, No. 5, p 28-33, May, 1985.

Descriptors: *Infrastructure, *Water conveyance, Management planning, Urban planning, Conveyance structures, Water rates, Economic aspects, Planning.

The problems of infrastructure in the water-supply systems of the United States tend to be concentrated in the older cities of Northeast, where deferred maintenance and unrealistically low water rates have created an accumulation of system problems. Four main areas that each utility manager should address before looking for assistance in resolving problems of inadequate and decaying infrastructure are: (1) an effective preventive maintenance program, (2) a capital program of replacement and improvement as part of the future planning process and annual budget, (3) an equitable water rate structure - sufficient to pay annual costs, including debt service, of a comprehensive rehabilitation program, and (4) a system of charges that places the burden of financing facility expansion on those customers causing the need. The infrastructure barriers are essentially internal to each utility. The ability to use external assistance exists, but for political and other reasons, such assistance may be severely limited in the future. As an enterprise, the water industry is uniquely capable of solving its infrastructure problem because of its particular internal ability to establish water rates that can produce a revenue stream sufficient to pay all operating costs, as well as debt service required to rehabilitate and expand deficient facilities. ALTERNATIVE SOLUTIONS,
Johns Hopkins Univ., Baltimore, MD. Dept. of Geography and Environmental Engineering.
J. J. Boland.
Water Engineering and Management, Vol. 132, No. 5, p 33-39, May, 1985. 3 Ref.

Descriptors: *Infrastructure, *Management planning, *Economic aspects, Funding, Privatization, Legal aspects, Planning.

Water/wastewater utilities with infrastructure problems are typically those in need of substantial amounts of capital. The solution to the capital problem consists of two steps: (1) increasing rates sufficiently to halt the erosion of existing capital and to provide for repayment of borrowed funds, and (2) raising needed capital from subsidies, debt proceeds, or current revenues. Within the public sector, subsidy may be disappearing as an option as federal and state government trim their budgets. Long-term debt, through such agencies as 'bond banks' or by conventional, but previously unused, debt sources is one alternative available to the utility manager. For systems with facilities in imminent danger of failure, or to keep capital costs low, short-term debt is appropriate. Sometimes market conditions may actually provide lower rates for short-term instruments. Privatization of all or part of the physical facilities is a method of financing that depends entirely on federal tax law, which provides tax benefits to those acquiring the utility. These indirect subsidies from the federal treasury may permit utilities to acquire needed facilties at a lower cost than would be possible under the public finance alternatives. Institutional changes may also help. For example, a utility could be merged with a stronger utility to provide improved credit and better cash flow. Horizontal mergers are frequently advocated to improve operational efficiency and quality of service, as well as to provide improved access to capital, whereas vertical mergers are often proposed as last-resort solutions to fiscal emergencies. BYZANTINE ART OF WATER UTILITY RATEMAKING,
Water and Wastewater Equipment Mfrs. Association, Washington, DC.
F. Summer.
Environmental Forum, Vol. 4, No. 1, p 32-38, May, 1985. 10 Ref.

Descriptors: *Economic aspects, *Water treatment, *Utilities, *Costs, Public policy, Management planning, Water distribution.

Factors affecting the setting of water rates are discussed. Water industry costs have two major sources: environmental and health-related requirements and the costs of repair and rehabilitation of facilities. Deferred maintenance is common among utilities, but nearly half of the utilities could eliminate their backlogs through stepped-up construction programs over a 10-yr period. Setting water rates involves a process of matching the costs of providing service to the unique economic, political, and social environments in which a utility provides service. Two methods are generally used for determining total revenue requirements: the case or budget basis and the utility basis. Equitable allocation of costs among customer classes required determination both of the amount of water required by each class and of the peak needs of each customer. Most rate structures used by water utilities include stepped decreases as consumption increases; different classes of customers create different load characteristics. Connection charges help finance new construction and recover some capital costs. Fire protection (hydrant) rates

depend on where a particular hydrant is located (public or private property) and who is responsible for its upkeep. Ultimately, public utility commissions control the rates for most investor-owned systems and for some publicly-owned utilities. The public and its representatives sometimes express the view that water is free, or that water rates should be limited, regardless of the utility's expense in providing it. Costs of water must reflect the benefits derived from it. (Rochester-IVI)

NEW RULES FOR NATIONAL FOREST WATER,
California Univ., Berkeley. Dept. of Forestry and Resources Management.
J. Romm, and K. Bartoloni.
Journal of Forestry, Vol. 83, No. 6, p 362-367, June, 1985. 4 Fig, 3 Ref.

Descriptors: *National forests, *Water rights, *Forests, *Legal aspects, Riparian rights, Organic Act, Federal Land Policy and Management Act, Multiple Use-Sustained Yield Act, Resource allocation, Water allocation.

The decision of the U.S. Supreme Court in the 'Rio Mimbres' case limited the federal reserved right to water, under which the Forest Service had been claiming water for all its various uses of reserved land. Based on an interpretation of the Organic Act of 1897, the court limited the Forest Service's claim to water to that necessary for maintaining timber supplies and favorable water flows. Other uses, such as recreation, fish and wildlife needs, and aesthetics, were not included. Four strategies have been employed by the Forest Service to attempt to regain lost water rights. First, a hydrological argument has been advanced, based on the 1897 Organic Act, that enough water must be allowed to flow through rivers to keep the drainage network in good condition. In California, the Forest Service has asserted its 'riparian rights' as a property owner, to which it is entitled under that states' laws. As a third strategy, the Forest Service is testing the extent of its powers to regulate private uses of national forest water under the Federal Land Policy and Management Act of 1976. Its permit authority under this act may allow it to confine the scope of private water use within national forest boundaries and to expand its control of water allocation. In a fourth strategy, the Forest Service is contending in court that the Multiple Use-Sustained Yield Act of 1960 implied the same reserved rights for 'supplemental' purposes after 1960 as the Organic Act implied for the maintenance of timber supplies and favorable stream flows. Other strategies available include exercising eminent domain power to buy water rights and various cooperative agreements with states and federal agencies for joint management of water and sharing of costs. SALINITY ISSUES AND WATER DEVELOPMENT IN THE GREEN RIVER BASIN, WYOMING,
Department of Energy, Morgantown, WV. Morgantown Energy Technology Center.
S. D. Cooke, and J. Ahern.
Water Resources Bulletin, Vol. 21, No. 2, p 217-223, April, 1985. 2 Fig, 11 Ref.

Descriptors: *Water resources development, *Salinity, *Green River Basin, *Wyoming, Water allocation, Colorado River Compact, Upper Colorado River Basin Compact, Appropriation, Downstream.

Water development in the Green River Basin of Wyoming is projected to increase salinity downstream in the Green River and Colorado River, and thereby increase salinity costs to users of water from these two rivers. Despite these water quality and economic impacts to downstream water users, Wyoming will probably be able to develop its currently unused but allocated water supplies of the Green River Basin. The Colorado River Compact and Upper Colorado River Basin Compact are binding, and protect Wyoming's share of the Colorado River System waters for future use. The argument that water may be used to greater profit downstream is not sufficient to reduce Wyoming's allocation. In addition, the no-injury rule under the appropriation doctrine of law does not appear to protect prior downstream appropriations from increasing salinity in this case. (Author's abstract)

FLOTATION THAT MIGHT SINK,
F. Pearce.
New Scientist, Vol. 106, No. 1452, p 16-19, April, 1985.

Descriptors: *Privatization, *Public policy, *Water authorities, *Organizations, *England, *Wales, Water treatment facilities, Water districts, Maintenance, Economic aspects, Infrastructure.

None of the 10 regional water authorities in England and Wales that the British government plans to sell to the private sector is without serious infrastructure problems in both the water supply and water treatment phases of its operations. The considerable age of many of the mains, reservoirs and treatment plants, and the fact that maintenance has been significantly curtailed as an economy measure since the mid-1970s, contribute to the major capital needs that these authorities have. Water supplies in many places have severe leaks, bacteriological standards are not met in some cases, Nais worms have been found in the water supply in Sussex, sewer collapses in Yorkshire (64 per 1,000 km of sewer), and problems with inadequate recordkeeping in Wales, are among the numerous problems facing the authorities involved. Many water supplies fail to meet European Economic Community standards. The water authorities (North West, Southern, Yorkshire, Thames, Welsh, South West, Severn Trent, Northumbrian, Wessex, and Anglian) have assets valued at 26 billion pounds sterling, but many of the authorities have hundreds of millions of pounds in deferred maintenance or capital spending that must be done to correct significant problems. In many areas the quality of both drinking water and effluent from treatment plants is declining rather than improving under current management. Investors may be reluctant to take on the responsibility of upgrading the seriously deteriorated facilities that would become theirs if they were to buy them from the government. (Rochester-IVI)

ALTERNATIVE APPROACHES TO ACID RAIN CONTROL,
E. M. Trisko.
Environmental Forum, Vol. 3, No. 12, p 18-23, April, 1985. 1 Fig, 1 Tab, 15 Ref.

Descriptors: *Acid rain, *Water pollution control, *Clean Air Act, *Legislation, Legal aspects, Air pollution, Nitrogen oxides, Sulfur dioxide, Organic compounds, Emission density zoning.

Because Section 126 of the Clean Air Act does not treat acid rain as a pollutant, downwind states have appeared to be at the mercy of upwind polluters. However, acid precipitation can be reduced by enforcing the existing Clean Air Act. At least two mechanisms are now available to EPA: a fine particulate matter standard for sulfates developed under Sections 108 and 109, and enforcement of Section 169A's visibility protection program. If Congress insists on a special legislative remedy for acid rain, existing Clean Air Act programs and principles could supply the foundation for an integrated approach to acid rain control and visibility enhancement. Compared to the emission reduction allocation methods in the principal House and Senate acid rain bills, a new approach emission density zoning would be more both with the Act's uniform standards- proach, and with current scientific unde of atmospheric transport and deposition rection of the Clean Air Act reautl debate may change as a result of new indication that emissions of nitrogen volatile organic compounds may have effect on forests. Eventually, Congress w address the major policy issue underlyin rain debate: whether the Clean Air Act protects the environmental values Con intends to protect. (Moore-IVI)

G THE CUMULATIVE EFFECTS OF
PRACTICES ON DOWNSTREAM
ECOSYSTEMS,
ssociates, Wenatchee, WA.

oil and Water Conservation, Vol. 40,
No. 2, p 237-241, March/April, 1985. 4 Fig, 4 Tab, 12 Ref.

Descriptors: *Model studies, *Forest management, *Environmental effects, Forest watersheds, Forestry, Watersheds, Management, Water quality, Water quantity, Ecosystems, Computer models.

By modeling key watershed parameters affecting the quantity and quality of water delivered to downstream ecosystems, the KWCEA (a Watershed Cumulative Effects Analysis) model provides an annual index of a watershed's hydrologic condition. The index value implies the cumulative-effects risk that must be assumed with past, current or future watershed forest practices. Of the seven model components, only two require professional judgement - the potential slope stability failure frequency and the time period for a disturbed area within a watershed to become hydrologically mature. Guides are provided to assist in making these judgements. A computer model greatly reduces the time needed to calculate the KWCEA values. The model is particularly useful for evaluating forest practice options within a watershed during planning. Potential levels of downstream impacts can be estimated. The worst-case KWCEA index value or the implied cumulative-effects risk can be calculated and compared with present or future scheduled levels of watershed activity. The output from the KWCEA model provides a much needed data base to coordinate forest activities among several landowners within a watershed. (Baker-IVI)

CHANGES IN SOIL CARBON AND NITROGEN DUE TO IRRIGATION DEVELOPMENT IN NEBRASKA'S SANDHILL SOILS,
Nebraska Univ.-Lincoln. Dept. of Agronomy.
M. A. Lueking, and J. S. Schepers.
Soil Science Society of America Journal, Vol. 49, No. 3, p 626-630, May-June, 1985. 2 Fig, 5 Tab, 22 Ref.

Descriptors: *Irrigation effects, *Soil chemistry, *Carbon, *Nitrogen, *Nebraska, Hydrolyzable nitrogen, Mineralizable nitrogen, Soil depth.

Carbon and N parameters were compared for non-developed and developed soils (predominantly mixed mesic, Typic Ustipsamments, and sandy, mixed mesic Entic Haplustolls). Soil samples were collected from four developed center pivot irrigation sites and from the nondeveloped corners at depth increments of 0- to 75-, 75- to 150-, and 150- to 300-mm. Total C, total Kjeldahl N (TKN), hydrolyzable N, and mineralizable N by autoclave and by 112-d incubation study were determined. Changes in TKN were not significant in the 0- to 75-mm, depth, but in the second depth increment, TKN increased with development (507 to 569 kg/ha). Total C also increased at this depth (5650 to 6400 kh ha-1). The C/N ratio increased with development in the surface 75 mm (11.5 to 12.2). Inorganic N increased in the top 300 mm due to development. Mineralizable N by both techniques increased in the 75- to 150- and 150- to 300-mm depth increments. Steady state values for ln TKN were calculated to be 6.6, 6.4, and 6.8 kg/ha for soil depth increments of 0- to 75, 75- to 150-, and 150- to 300-mm, respectively. The ln total C steady-state values were 9.1, 8.8, and 9.1 kg/ha. In some cases, undeveloped soil contained more N and C than these steady-state values, suggesting that development tended to decrease the soil test values. If the undeveloped soil was lower in N or C than the steady-state value, development tended to increase the test value. Total C, TKN, hydrolyzable N, mineralizable N (both techniques), and inorganic soil N were all highly correlated. Changes in TKN and total C were not correlated to landscape position or time since development. (Author's abstract)

NET BENEFIT MODEL FOR RECREATION PLANNING AT DRINKING WATER RESERVOIRS,
Fitchburg, MA.
J. J. Behan, M. Gross, and L. R. Klar, Jr.
Water Resources Bulletin, Vol. 21, No. 2, p 297-309, April, 1985. 3 Fig, 6 Tab, 23 Ref. Department of the Interior project B-078-MASS.

Descriptors: *Recreation, *Environmental effects, *Reservoirs, *Model studies, *Planning, Quabbin Reservoir, Massachusetts, Water quality control, Cost-benefit analysis, Carrying capacity, Multipurpose reservoirs, Nutrients, Drinking water.

A management model was developed for determining levels of recreation activities at public drinking water reservoirs. Quabbin Reservoir, located in central Massachusetts, served as a case study for the model. An interdisciplinary research team was formed to study the impact of selected recreation activities on water quality, public demand and willingness to pay for selected recreation activities, carrying capacity constraints, and the economic cost/benefits associated with increases in recreation at the Quabbin Reservation. Study variables were integrated into a quadratic programming model, producing the number of participants that corresponds to maximum net benefits for specific development packages on design days. The reaction mix associated with maximum net economic benefits was found to be cost-effective (assuming the use of reasonable entrance fees) and not deleterious to water quality. However, as a result of the findings of a related study, it was recommended that nutrients, particularly from wastewater, not be permitted to enter the reservoir, since the current phosphorous level may be at a critical point. Management techniques that would safeguard against the occurrence were recommended. The model was sensitive to management objectives; recommendations were limited to activities that would not lower the existing high quality of Quabbin water. (Author's abstract)

IMPACT OF HYDRAULIC WORKS ON WATER QUALITY, PART TWO,
Electricite de France, Chatou. Direction des Etudes et Recherches.
R. Gras, and J. P. Albignat.
International Water Power and Dam Construction, Vol. 37, No. 5, p 41-46, May, 1985. 11 Fig, 1 Tab, 12 Ref.

Descriptors: *Environmental effects, *Water quality, *Hydraulic structures, Mathematical models, Navigation, Irrigation, Flood control, Ecological effects, Management.

All hydraulic projects, including those to meet quantitative needs (navigation, irrigation, and flood control) have a definite effect on the quality of water, but the magnitude of change to an ecosystem is not always related to the size of the associated hydraulic project. Appropriate design or good management of a project can limit a particular effect on the water quality, although it is necessary to have criteria to follow. Mathematical models allow the problems of conflicting criteria to be analyzed with respect to the estimation of the effects, or to the improvement of the design and selection of proper management. The actual scope for adapting management to meet water quality criteria is limited. (Moore-IVI)

HYDROLOGIC AND VEGETATIONAL CHANGES RESULTING FROM UNDERGROUND PUMPING AT THE CYPRESS CREEK WELL FIELD, PASCO COUNTY, FLORIDA,
Southwest Florida Water Management District, Brooksville.
T. F. Rochow.
Florida Scientist, Vol. 48, No. 2, p 65-80, 1985. 4 Fig, 2 Tab, 17 Ref.

Descriptors: *Wells, *Environmental effects, *Vegetation, *Hydrology, *Cypress Creek Well Field, *Florida, Pumping, Cypress domes, Marshes, Surface water, Aquatic plants, Wetlands.

From 1975-1982 the hydrologic and vegetation response of selected cypress domes and marshes in the Cypress Creek Well Field (Florida) to deep underground pumping was compared to similar sites far removed from water production activities. After water production began, 5 of the 7 wellfield study sites experienced 1 to 5 consecutive years without standing surface water. Control sites had some surface water each year despite differences in yearly precipitation. Wellfield study sites with at least 2 yr without surface water showed a complete loss of typical deep-water aquatic plant species such as pickerelweed (Pontederia cordata) and rush (Juncus repens). At various wellfield impacted sites, maidencane (Panicum hemitomon), willow (Salix caroliniana), blue maidencane (Amphicarpum muhlenbergianum), dog fennel (Eupatorium capillifolium) and buttonweed (Diodia virginiana) became abundant. Vegetation at the control sites was quite stable from 1 yr to the next. (Author's abstract)

DENSITY OF PRECIPITATION CHEMISTRY NETWORKS,
Kozponti Cegkorfizikai Intezet, Budapest (Hungary).
L. Haszpra.
Environmental Monitoring and Assessment, Vol. 5, No. 2, p 185-197, June, 1985. 4 Fig, 2 Tab, 13 Ref, 1 Append.

Descriptors: *Precipitation chemistry, *Density, *Network design, Sulfates, Nitrates, Ammonium, Calcium, Water pollution sources, Mathematical models, Statistical models.

Using a mathematical-statistical method the accuracy of the precipitation chemistry networks of different densities were studied. The necessary density of the networks was estimated. The basic principle of network planning methods is the following: the meteorological network covering a given area has to make it possible to determine the value of the meteorological element for any point or any part of the area with the required accuracy. The error of the interpolation for any point or that of the areal averaging for any part of the area must not exceed the maximum value permitted by the investigations. Using Scandinavian precipitation chemistry data the dependence of the accuracy of the interpolation and areal averaging of sulfate, nitrate, ammonium ion and calcium ion contents of precipitation water on the density of the network and on the size of the area considered is studied. The density of networks operation with a given accuracy can be determined as a function of the area. As an example the density of the networks determining the annual and mothly areal SO4(-2) deposition as well as the point values of the monthly SO4(-2) concentration with an accuracy of 1%, 25% and 30%, respectively is calculated. The accuracy provided by such networks for other components in precipitation water is also studied. (Baker-IVI)

ENVIRONMENTAL AUDIT. II. APPLICATION TO STREAM NETWORK DESIGN,
Minnesota Univ., St. Paul. Dept. of Forest Resources.
J. A. Perry, D. J. Schaeffer, H. W. Kerster, and E. E. Herricks.
Environmental Management, Vol. 9, No. 3, p 199-207, May, 1985. 5 Tab, 22 Ref.

Descriptors: *Environmental audit, *Network design, *Streams, Idaho, Sampling, Data acquisition, Data interpretation, Water quality, Decision making, Monitoring, Planning, Management.

The planning and execution of water quality management programs requires careful collection and analysis of data coupled with a systematic review and analysis of programmatic success. The environmental audit is a tool which facilitates improved water quality planning and management. This article demonstrates the utility of the environmental audit by reviewing portions of a comprehensive review of the water quality management program for the state of Idaho. The audit is a tool which forces careful design of a sampling program before data are collected. In the audit approach, program objectives are clearly stated prior to initiation of sampling. Stated objectives are also evaluated regularly to identify tension points, that is, conflicts between expectations and reality. In the example taken from Idaho, a management review team followed a directive to redesign the water quality monitoring program. A summary of the redesign as proposed by that team is presented to illustrate the results of a typical review of monitoring programs. That summary is followed by an example of how the proposed program would differ if the audit approach had been used. The two approaches offered both coincident and conflicting recommendations. Management review team and audit recommendations for lake sampling programs were similar even though a different process was used to develop the recommendatons. The most striking contrast between the two results lies in the review team's approach to the problem. The directives followed, and the team's responses, concentrate on tools, such as increasing biological monitoring or reliance on monthly BWMP stations. In contrast, the audit results stress addressing management questions for which clear objectives have been stated, depending on specific tools only as needed to meet stated objectives. Although the audit does integrate externalities in its structure, it is little affected by economic or political influences. A major strength of the audit approach is its ability to provide defensible data for management decision making. (Author's abstract)

USE OF SEEPAGE METERS TO ESTIMATE GROUNDWATER NUTRIENT LOADING TO LAKES,
Florida Inst. of Tech., Melbourne. Dept. of Environmental Sciences and Engineering.
T. V. Belanger, and D. F. Mikutel.
Water Resources Bulletin, Vol. 21, No. 2, p 265-272, April, 1985. 3 Fig, 6 Tab, 22 Ref.

Descriptors: *Seepage meters, *Nutrients, *Lakes, *Seepage, Groundwater movement, Nitrogen, Phosphorus, Lake sediments, East Lake Tohopekaliga, Florida.

Data from a study on East Lake Tohop Florida, indicate that the seepage meter m ment method may often overestimate nutri tributions to lakes. Nutrient loading data f method and a method employing lakeside p ter nutrient data and seepage meter flows v comparable. Seepage nutrient loading fr meter and piezometer methods comprised 18% of the nitrogen budget and 38 and 9% phosphorus budget, respectively, for Ea Tohopekaliga. In terms of water, grou seepage accounted for only 14% of the to to the lake. It is felt that some of the pas using the seepage meter method to estima ent loading may be in error due to reasons to the enclosure of lake sediments by the m the accompanying anaerobic conditions quickly result. WHAT'S GOING ON UNDER CHICAGO,
De Leuw, Cather and Co., Chicago, IL.
E. McGuire.
Pollution Engineering, Vol. 17, No. 2, p 29-32, February 1985. 2 Fig.

Descriptors: *Chicago, *Calumet Pumping Station, *Illinois, *Tunnels, *Pumping stations, Pumps, Sewers, Main sewers, Wastewater facilities, Water transport.

The Calumet Pumping Station, a part of the Chicago (Illinois) Tunnel and Reservoir Plan (TARP), uses six computer-controlled centrifugal pumps with a combined capacity of 280,000 gallons per minute (gpm) to deliver wastewater at a suction head varying from +5 to -322 ft Chicago City Datum. Unlike a conventional lift station, the Calumet Pumping Station, which will go on line in early 1985, will discharge directly into the sewage treatment works, and has been designed to function on flow demand rather then maintenance of a wet shaft water level. The system includes two pump rooms, located 350 ft below grade, interconnecting shafts and an electric substation, and various above-ground support facilities. The pumps selected include two types: four with infinitely variable-speed transmissions coupled to 6,000 horsepower (hp) synchronous motors, with rotation speeds from 0-600 revolutions per minute, and two constant-speed units driven by 2,500 hp induction motors. The control system allows operation automatically from a remote control room, manually from the same control room, or locally from control panels located adjacent to the equipment being controlled. Six ultrasonic flow meters provide continuous flow measurements to computers, which govern the system and record 44 separate functions, each of which can be assigned to trend recorders for analysis as part of the preventive maintenance program. Quick-closing valves (84 inches in diameter) are provided for security against flooding of the pump room, and fire, hazardous gas, and oxygen deficiency are monitored, with automatic responses to an emergency programmed into the controls of support systems. Trash removal is by bar screens, screen rakes, and skip hoists, with disposal off site. A 16-foot diameter equipment shaft is provided for each pump room, with a 40-ton capacity overhead crane for moving equipment. (Rochester-IVI)

SUPERHYDRO,
A. Danilevsky.
Civil Engineering, Vol. 54, No. 11, p 54-57, November, 1984. 1 Fig.

Descriptors: *Hydroelectric plants, *Pumped storage, *Dams, *Bath County, *Virginia, Reservoirs, Tunnels, Electric power production.

When the Bath County (Virginia) Pumped Storage Project is completed in 1986, it will be the world's largest, with six turbine/pump generator/motor units rated at 2,100 Mw. Bath County is in the James River basin, high in the ridges and valley of the Appalachian Mountains. Conduits in rock connect the upper lake to the lower one with a drop of about 1,200 ft from the upper lake to powerhouse over a more than 8,000 ft route. Two dams are involved, both of earthfill/rockfill type with impervious cores. The upper dam is 460 ft high and 2,200 ft long; the lower dam is 150 ft high and had a spillway designed to carry 38,000 cu ft/sec. The reinforced concrete powerhouse is designed to resist being submerged to 6 ft above its roofline, with only the parapet protecting it from flooding. The main generator hall contains six bays, each with a reversible turbine/pump connected to a reversible generator/motor unit. Each unit has a rated 3,350 Mw generating capacity at a rated 1,262 ft head and required 410 Mw when reversed. A 500 kv switchyard is on the roof deck, and nine 300 Mva transformers are upstream in the powerhouse yard. Three 28.5 ft diameter tunnels lined with 18 in concrete will be used to connect the upper and lower reservoirs. A 986-ft vertical shaft about midway along the tunnel accounts for most of the vertical drop to save excavation costs. Surge chambers, located just upstream from the vertical shafts, are 330 ft high and 44 ft in diameter. (Rochester-IVI)

ITAIPU, SOUTH AMERICA'S GRANDE DAME,
Itaipu Binacional, Rio de Janeiro (Brazil).
J. R. Cotrim, H. W. Krauch, and G. S. Sarkaria.
Civil Engineering, Vol. 54, No. 12, p 40-43, December, 1984. 2 Fig.

Descriptors: *Itaipu, *Brazil, *Paraguay, *Parana River, *Hydroelectric plants, *Hollow dams, Costs, Dam construction, Construction costs, Dams.

The world's highest and largest hollow gravity dam was built at Itaipu, on the Parana River between Brazil and Paraguay. The structure is 643 ft high and 25,400 ft long. Key elements in the success of the project were timely diversion of the river through a single diversion channel, which prevented an 8-mo delay in construction that would have cost $300 million in interest charges, construction of suitable cofferdams of 295 ft and 246 ft high, and maintenance of minimum flow as the reservoir filled. The selection of the hollow gravity design saved 2.1 million cubic yards of concrete compared to a solid gravity design. An unexpected combination of flooding conditions necessitated changes in the planned filling procedure; all 14 spillway gates, each 65.6 x 70 ft, were opened 15 days after storage began. The Itaipu spillway will be required to operate continuously until more power units can be installed. The maximum spillway discharge so far has been 1,348,000 cu ft/sec, 61% of the design capacity. Two 700 Mw generating units became operational in 1984; all 18 units will be operational in 1990 when the project capacity will be 12,000 Mw. The Itaipu project, when completed, is estimated to cost $15 billion (1983 dollars), of which about 36% is for interest and financial charges. The system will operate as a base-load power plant with very little drawdown, which will ensure high operational efficiency and low maintenance costs. (Rochester-IVI)

PROPORTIONAL WEIRS FOR STORMWATER POND OUTLETS,
EGC-Southwell, Inc., Englewood, CO.
A. Sandvik.
Civil Engineering, Vol. 55, No. 3, p 54-56, March, 1985. 4 Fig.

Descriptors: *Weirs, *Proportional weirs, *Storm runoff, *Detention reservoirs, Construction, Costs, Flood protection, Dams.

A proportional weir to control outflow from a stormwater pond near Denver, Colorado, provides a way to restrict floodwater release from a developed site to historic flows, thus preventing downstream property damage and resulting legal claims. The proportional weir uses an outlet that decreases in width towards its top, with cross-sectional dimensions adjusted so that there is a linear relationship between head and discharge. The weir was sized based on the maximum head available in the pond and the maximum discharge that the weir was allowed to pass (100-yr historic). The approximate maximum storage volume for the stormwater pond was found by determining the areas between the historic and post-development storm hydrographs. The proportional weir outlet structure was constructed of reinforced concrete, with each side supported by a counterfort extending perpendicular to the weir in the upstream direction. The weir edge was constructed by bending two steel channel sections to the dimensions outlining the weir.

An energy dissipator consisting of 18-24-in riprap was placed immediately downstream, depressed 4 ft. In 1982, the weir cost $43,000, with an additional $118,000 required for a flashboard dam. Cost of grading the detention pond was additional. (Rochester-IVI)

HYDRAULIC FILL DAM MADE EARTHQUAKE RESISTANT,
East Bay Municipal Utility District, Oakland, CA.
H. J. Billings.
Civil Engineering, Vol. 55, No. 6, p 56-59, June, 1985. 4 Fig.

Descriptors: *Hydraulic-fill dams, *Earthquake engineering, *San Pablo, *California, Dams, Geologic faults, Construction criteria, Buttress dams.

An earthfill buttress, combined with a sand (drain) blanket, was used to protect the dam at the San Pablo (California) reservoir from the potential effects of earthquakes. The dam, built in 1919-21 by hydraulic fill methods, lies relatively close to the active Hayward, Calaveras, and San Andreas faults. Of 20 originally studied construction alternatives, seven were considered feasible: an upstream rockfill buttress, a new dam at one of three locations, an upstream earthfill buttress, a replacement of the existing dam, and a partial replacement of the existing dam. The upstream fill buttress was not only the most economical, but was most desirable from engineering and environmental viewpoints. To install the 50-60 ft-thick buttress, the reservoir had to be dewatered. Water supply was ensured by constructing a temporary pumping plant and a temporary pipeline running along the reservoir shoreline and into the raw water line below the reservoir. The discovery that porewater pressures equal to 100% of the amount required for liquefaction could occur during an earthquake both within the dam and within the impervious buttress necessitated installation of drains. A 3 ft-thick sand blanket was installed, complete with three new vertical vents, between the dam and the new buttress, to ensure that pore pressures would be released into the reservoir. Vertical sand drains were also drilled within the original dam cross-section. The project cost $16.4 million, of which $3.3 million was for the bypass waterway system. (Rochester-IVI)

MODELLING VIBRATION AND VORTEX FORMATION AT PIEDRA DEL AGUILA,
Ecole Polytechnique Federale de Lausanne (Switzerland). Lab. d'Hydraulique.
J. Bruschin.
International Water Power and Dam Construction, Vol. 37, No. 5, p 21-24, May, 1985. 9 Fig, 4 Ref.

Descriptors: *Vibrations, *Vortices, *Piedra del Aguila, *Dams, Service gates, Cavitation, Spills.

Model tests were used to successfully define and correct vibration and vortex formation problems associated with the Piedra del Aguila dam. The Piedra spillway uses 15 x 18.5 m radial gates and 3 x 2 m maintenance and service gates at the bottom outlet. Runs with the spillway on the general 1:130 model demonstrated active, partly air-entraining, vortices in the inlet bays upstream from the spillway crest. Observations were conducted and vortices were ranked in terms of strength, size, and persistency, scale effects were estimated, and vortex-suppressing measures were proposed and tested. Modification of bay or pier shape was eliminated as a potential solution after testing, but vortex-suppressing collars around the pier heads efficiently suppressed the vortices. A boundary layer suction device also was designed and tested. Testing at scale 1:25 showed that the device worked smoothly if well submerged, even under rather high heads. Systematic tests were conducted with the service gate opened at 31.49% and 77% of the total aperture while the maintenance gate was progressively lowered, because this operational procedure seemed most likely to uncover vibration and cavitation risks according to the results of earlier tests. Large sub-atmospheric pressures with important fluctuations (standard deviation = 1/3 of the average pressure value) were found between the two gates. It was observed, however, that a very small displacement of the maintance gate produced an abrupt change in the pressure pattern, so this condition was discarded from the list of high-risk situations being considered. SIMPLE GOVERNING AND SURGING SIMULATION, PART ONE,
Queen's Univ., Kingston (Ontario). Dept. of Mechanical Engineering.
R. A. Chaplin.
International Water Power and Dam Construction, p 25-28, May, 1985. 2 Fig.

Descriptors: *Surges, *Governing stability, *Turbines, *Simulation, Mathematical equations, Hydroelectric plants, Hydraulic transients, Computers.

This article considers the governing stability of hydro turbines and the hydraulic transients in waterways following various changes in operating conditions. The appropriate mathematical equations are derived to give the necessary background for an overall understanding of the formulation of the expressions and physical phenomena. The equations are then put together to create a simple but effective method of determining the overall transients occurring in hydro powerplant following a disturbance. The resultant computer program (to be published in Part Two) can be used on any desk top computer to study various elementary transients. The emphasis is on simplicity since the program lends itself by expansion, to reasonable degree of elaboration. (Author's abstract)

HYDRO-PLANT UPGRADES YIELD RELIABLE, COST-EFFECTIVE KILOWATTS,
J. Makansi.
Power, Vol. 129, No. 5, p 61-63, May. 1985. 6 Ref.

Descriptors: *Hydroelectric plants, *Costs, *Upgrading, Capacity, Power plants, Turbines, Generators, Maintenance.

Older hydroelectric plants often have additional capacity available if steps are taken to upgrade equipment to the best modern standards. Efficiency of turbine runners may be improved by replacing carbon steel runners with those made of stainless steel (integrally cast). Uprating of a turbine/generator usually means more water flow through the unit, which generates a requirement for upgrading of other elements, such as wicket gates, seals, and operating procedures intended to balance runner cavitation, output, and minimum tailwater elevation. The Electric Power Research Institute and others recommend that generator stator windings be subjected to a comprehensive program of dielectric measurements, supplemented by visual inspections at regular intervals, so that trends in performance and condition can be used to predict when rewinding is necessary. Uprating a turbine/generator may necessitate improving of coupling bolts, rotor hubs, spider assemblies, and shafts because these components may be subjected to greater stresses and thermal loads. The thrust bearing load should also be examined when upgrading a system. Modern instrumentation provides many more measurements than are normally offered with older systems. (Rochester-IVI)

W86-00718 5B

AIR STRIPPING
Removing VOC from Groundwater; Pilot, Scale-up, and Operating Experience,
W86-00816 5F

Packed Tower Aeration Strips Trichloroethylene from Groundwater,
W86-00817 5F

AIR TEMPERATURE
Influences of Snow Cover and Soil Moisture on Monthly Air Temperature,
W86-00860 2A

ALASKA
Analysis of Precipitation Chemistry Data from Alaska,
W86-00659 2K

Gold-Mining Effects on Stream Hydrology and Water Quality, Circle Quadrangle, Alaska,
W86-00785 4C

Gold-Mining Effects on Heavy Metals in Streams, Circle Quadrangle, Alaska,
W86-00786 5C

ALDRIN
Metabolism of Aldrin by the Freshwater Planarian Phagocata gracilis,
W86-00693 5C

Persistence of Aldrin in Flooded Soil under the Cover of Rice,
W86-00875 5B

ALGAE
Influence of Oil Refinery Effluents on the Structure of Algal Communities,
W86-00623 5C

Toxicity and Accumulation of Copper and Cadmium in the Alga Scenedesmus obliquus LH,
W86-00697 5C

ALGAL GROWTH
Water Quality Model for Lake Kuortaneenjarvi, a Polyhumic Finnish Lake,
W86-00677 2H

ALKALINE PHOSPHATASE
In Vitro Effect of Mercuric Chloride on Acid and Alkaline Phosphatase Activity of a Freshwater Prawn,
W86-00625 5C

ALLIUM TEST
Allium Test on River Water from Braan and Saxan Before and After Closure of a Chemical Factory,
W86-00667 5A

ALLUVIAL FANS
Alluvial Fans: Novel Flood Challenge,
W86-00885 2E

ALUM
Distribution of Aluminum in the Tissues of Three Fish Species,
W86-00621 5C

ALUMINUM
Distribution of Aluminum in the Tissues of Three Fish Species,
W86-00621 5C

Influence of pH on the Binding Capacity and Conditional Stability Constants of Aluminum and Naturally-Occurring Organic Matter,
W86-00773 2K

Removal of Naturally Occurring Compounds by Coagulation and Sedimentation,
W86-00855 5F

AMINOCARB
Distribution and Persistence of Aminocarb in Stream Water, Sediment and Fish After Application of Three Matacil Formulations,
W86-00811 5B

Sorptive Capacity of an Aquatic Macrophyte for the Pesticide Aminocarb,
W86-00812 5A

ANAEROBIC CONTACT DIGESTION
Thermophilic Anaerobic Contact Digestion of Palm Oil Mill Effluent,
W86-00744 5D

ANAEROBIC DIGESTION
Role of an Anaerobic Stage on Biological Phosphorus Removal,
W86-00738 5D

Batch Anaerobic Methanogensis of Phenolic Coal Conversion Wastewater,
W86-00743 5D

Structured Modeling of the Anaerobic Digestion of Biomass Particulates,
W86-00848 5D

Performance of an Upflow Anaerobic Reactor Combining a Sludge Blanket and a Filter Treating Sugar Waste,
W86-00889 5D

Anaerobic Pretreatment Reduces Mill Costs, Improves Effluent Quality,
W86-00890 5D

Anaerobic Wastewater Treatment System Operates at Very Low Cost,
W86-00893 5D

ANAEROBIC RETENTION TIME
Influence of Extended Anaerobic Retention Time on the Performance of Phoredox Nutrient Removal Plants,
W86-00739 5D

ANIMAL BEHAVIOR
Effects of Cadmium and Copper on Chemotaxis of Marine and Freshwater Ciliates,
W86-00696 5C

ANIMAL GROWTH
Growth Inhibition and Recovery in Mussels (Mytilus edulis) Exposed to Low Copper Concentrations,
W86-00668 5C

Effect of Velocity of Water Flow on Growth of Colonial Hydroids (Hydrozoa, Thecaphora),
W86-00722 2H

ANIMAL PHYSIOLOGY
Metabolism of Aldrin by the Freshwater Planarian Phagocata gracilis,
W86-00693 5C

ANIMAL TISSUES
Organochlorine Residues in Animals from Three Louisiana Watersheds in 1978 and 1979,
W86-00691 5B

ANION-EXCHANGE RESINS
Separation and Determination of Selenium(IV) in Environmental Water Samples by an Anion-Exchange Resin Modified with Bismuthiol-II and Diaminonaphthalene Fluorophotometry,
W86-00825 5A

ANTARCTIC
Trace-Metal Concentrations in Sediments from Two Closed-Basin Lakes. Antarctica,
W86-00770 2H

APPALACHIANS
Acidification of Southern Appalachian Lakes,
W86-00663 5B

AQUACULTURE
Freshwater Aquaculture in China: Ecosystem Management for Survival,
W86-00664 2H

AQUATIC ANIMALS
Abiotic and Hydrobiologic Characteristics of the Mediterranean Running Waters (Caracteristiques Abiotiques and Hydrobiologiques des Eaux Courantes Mediterraneennes),
W86-00919 2H

AQUATIC ENVIRONMENT
Rate of Bacterial Mortality in Aquatic Environments,
W86-00777 2A

AQUATIC INSECTS
Influence of Development of the River Widawka on the Ephemeroptera Fauna (Influence des Amenagements de la Riviere Widawka sur la Faune des Ephemeropteres),
W86-00914 5C

AQUATIC PLANTS
Historical Changes in Submerged Macrophyte Communities of Upper Chesapeake Bay,
W86-00828 2H

Aquatic Angiosperm Communities from Lochs on Rhum,
W86-00906 2H

AQUIFERS
Step-Drawdown and Constant-Rate Pumping Tests,
W86-00712 2F

Fossil Water under the Sinai-Negev Peninsula,
W86-00911 2F

AROMATIC COMPOUNDS
Potential Use of Enzymes for Removal of Aromatic Compounds from Water,
W86-00753 5F

ARSENIC
Mobility of Zinc, Cadmium, Copper, Lead, Iron and Arsenic in Ground Water as a Function of Redox Potential and pH,
W86-00706 5B

ARSENIC COMPOUNDS
Removal of Arsenic from Geothermal Fluids by Adsorptive Bubble Flotation with Colloidal Ferric Hydroxide,
W86-00662 5D

ASBESTOS
Asbestos in Drinking Water
W86-00853 5B

ATTITUDES
Farmers' Attitudes Toward Nonpoint Pollution Control and Participation in Cost-Share Programs,
W86-00782 5G

AUSTRALIA
Rain Estimation in Extratropical Cyclones Using GMS Imagery,
W86-00859 2B

BACTERIA
Distribution Pattern of Denitrifying Ba
Fish Ponds of Differing Farming Mana
W86-00622

Bacteriological Survey of Two Acid-
Lakes in the Poconos before Limestone
tion,
W86-00634

Elimination of Viruses and Indicator Ba
Each Step of Treatment During Prepa
Drinking Water at Seven Water Tr
Plants,
W86-00775

Rate of Bacterial Mortality in Aquatic
ments,
W86-00777

Microbiological Quality of Recreational
in the Pacific Northwest,
W86-00840

BACTERIAL
Bacterial Adsorption and Suspended Pa
Urban Stormwater,
W86-00842

BACTERIAL TOXINS
Destroying Pyrogens in Water,
W86-00870

BANK EROSION
Bank-Erosion Processes in a Cool-Te
Environment, Orwell Lake, Minnesota,
W86-00898

BARCELONA
Factors Influencing the High Content
minated Trihalomethanes in Barcelona'
Supply (Spain),
W86-00727

BARNACLES
Growth in Biomass of Balanus balanoide
at Various Current Velocities,
W86-00721

BASS
PCBs in Striped Bass Collected fr
Hudson River, New York, During Fa
W86-00695

BATH COUNTY
Superhydro,
W86-00883

BAYOU PLAQUEMINE-BRULE
Organochlorine Residues in Animals fro
Louisiana Watersheds in 1978 and 1979,
W86-00691

BAYS
Effects of Treated Sewage Effluent a
Bottom Mud on Growth of Marine Phyt
ton,
W86-00616

BENTHIC FAUNA
Macrobenthic Invertebrates of a Pe
Stream in Southern Nigeria,
W86-00652

BENTHOS
Benthos-Plankton Relationship Upstre
Downstream of a Blackwater Impoundm
W86-00620

Organic Matter in Gravel Streams (Pro
TRODAT-LUNZ),
W86-00913

G CAPACITY
ce of pH on the Binding Capacity and onal Stability Constants of Aluminum turally-Occurring Organic Matter, 0773 2K

UMULATION
y Cycle in Lakes; Some New Hypoth- 681 5B

and Accumulation of Copper and Cad- n the Alga Scenedesmus obliquus LH, 597 5C

Y
f Sulfite Dechlorination on the Accumu- f Waterborne Lead by Rainbow Trout gairdneri), 15 5A

for the Toxicity of Chemicals with Te- na pyriformis, 11 5A

Bioassay of 11 Pesticides Using Larvae Mosquito, Wyeomyia smithii (Diptera:), 13 5A

rm Test for Predicting the Potential of cs to Impair Reproductive Success in 4 5A

ICAL OXYGEN DEMAND
Determination of the Optimal Sample condary Effluent BOD5 and SS, 3 5A

nalysis of BOD and Nitrogen Removal ation Ditch, 5 5D

S
Biofilter Process for Wastewater 5D

TORS
vation of Pathogenic and Indicator nisms, 5D

LOGY
gy of Harveys Lake, 2H

L TREATMENT
Treatment of Landfill Leachates, 5D

Removal of Phosphorus From 5D

L WASTEWATER TREATMENT
Soluble Substrates in Fixed Films, 5D

Load Fluctuations on the Effluent on Produced by Fixed-Film Reac- 5D

Nitrite Occurrence in Biological Treatment Systems, 5D

e Anoxic-Aerobic Systems for Bio- tment of Coke Plant Wastewaters, 5D

omass of Balanus balanoides Young urrent Velocities, 2H

Structured Modeling of the Anaerobic Digestion of Biomass Particulates, W86-00848 5D

Performance of an Upflow Anaerobic Reactor Combining a Sludge Blanket and a Filter Treating Sugar Waste, W86-00889 5D

BIOTIC INDEX
Chemical-Physical Changes Associated With Environmental Gradients in the Oka River Basin, W86-00916 2H

BISMUTHIOL-II
Separation and Determination of Selenium(IV) in Environmental Water Samples by an Anion-Exchange Resin Modified with Bismuthiol-II and Diaminonaphthalene Fluorophotometry, W86-00825 5A

BLACK CREEK
Benthos-Plankton Relationship Upstream and Downstream of a Blackwater Impoundment, W86-00620 6G

BLACKLICK CREEK WATERSHED
Watershed Planning for Acid Mine Drainage Abatement, W86-00787 4D

BLEACHING WASTES
Ion Exchange Potentially Effective in Reducing Effluent from Bleach Plant, W86-00892 5D

BOTTOMLANDS
Bottomland Vegetation Distribution Along Passage Creek, Virginia, In Relation to Fluvial Landforms, W86-00826 2H

BOUND MOISTURE
Determination of Moisture in Solids, W86-00644 2G

BRAAN
Allium Test on River Water from Braan and Saxan Before and After Closure of a Chemical Factory, W86-00667 5A

BRAZIL
Itaipu, South America's Grande Dame, W86-00886 8A

BRITISH COLUMBIA
Stochastic Flood Analysis in a Region of Mixed Generating Processes, W86-00646 2E

BROMINATED TRIHALOMETHANES
Factors Influencing the High Content of Brominated Trihalomethanes in Barcelona's Water Supply (Spain), W86-00727 5B

BRUCE LAKE
Bacteriological Survey of Two Acid-Stressed Lakes in the Poconos before Limestone Application, W86-00634 5C

BULRUSHES
Influence of Salinity on Scirpus americanus Tidal Marshes in the St. Lawrence River Estuary, Quebec, W86-00902 2L

CADMIUM
Effects of Cadmium and Copper on Chemotaxis of Marine and Freshwater Ciliates, W86-00696 5C

Toxicity and Accumulation of Copper and Cadmium in the Alga Scenedesmus obliquus LH, W86-00697 5C

Mobility of Zinc, Cadmium, Copper, Lead, Iron and Arsenic in Ground Water as a Function of Redox Potential and pH, W86-00706 5B

Effect of Aeration, Cadmium Concentration, and Solids Content on Acid Extraction of Cadmium from a Municipal Wastewater Sludge, W86-00846 5D

CADMIUM SULFATE
Binding of Cadmium, Copper, and Lead Ions by Modified Cellulosic Materials, W86-00692 5D

CALCIUM
Effects of Some Divalent Metals on Cardiac and Branchial Ca2+-ATPase in Freshwater Fish Saccobranchus fossilis, W86-00880 5C

CALIFORNIA
Alluvial Fans: Novel Flood Challenge, W86-00885 2E

Hydraulic Fill Dam Made Earthquake Resistant, W86-00888 8A

CALUMET PUMPING STATION
What's Going on Under Chicago, W86-00767 8A

CAPE MAY COUNTY
Enclosed Vessel Composting Begins at Cape May County, W86-00713 5E

CARBAMATES
Microarray Electrochemical Flow Detectors at High Applied Potentials and Liquid Chromatography with Electrochemical Detection of Carbamate Pesticides in River Water, W86-00820 7B

CARBOFURAN
Effect of Safe Concentrations of Some Pesticides on Ovarian Recrudescence in the Freshwater Murrel, Channa punctatus (Bl.): A Quantitative Study, W86-00872 5C

CARBOHYDRATES
Effects of Available Dietary Carbohydrate and Water Temperature on the Chronic Toxicity of Waterborne Copper to Rainbow Trout (Salmo gairdneri), W86-00630 5C

CARBON
Changes in Soil Carbon and Nitrogen Due to Irrigation Development in Nebraska's Sandhill Soils, W86-00703 6G

Effect of Drought on Metabolism and Partitioning of Carbon in Two Wheat Varieties Differing in Drought-Tolerance, W86-00907 2I

CARBON ADSORPTION ISOTHERM TEST
Carbon Adsorption Isotherm Test for Volatile Organic Chemicals in Water, W86-00845 5A

CARBONIZED COAL PRODUCTS
Carbonized Coal Products as a Source of Aromatic Hydrocarbons to Sediments from a Highly Industrialized Estuary, W86-00896 5B

CARBOZON
Alluvial Fans: Novel Flood Challenge, W86-00885 2E

CARP
Effect of pH on Toxicity of Sodium Pentachlorophenate to Fry of Common Carp in Softwater,
W86-00626 5C

Studies on the Sequence of 2,6-Diisopropylnaphthalene Metabolite Formation Using Carp Hepatocyte,
W86-00879 5C

CESIUM RADIOISOTOPES
Distribution of gamma Exposure Rates In a Reactor Effluent Stream Flood Plain System,
W86-00821 5B

Radiocesium Levels in Irish Sea Fish and the Resulting Dose to the Population of the Irish Republic,
W86-00822 5B

CHANNEL MORPHOLOGY
Seepage-Limitation Optimization of the Shape of An Irrigation Channel by the Inverse Boundary-Value Problem Method,
W86-00869 3F

CHAPARRAL
Seasonal and Diurnal Water Relations Adjustments in Three Evergreen Chaparral Shrubs,
W86-00827 2I

CHEMICAL ANALYSIS
Chemical Study of the Shohola Creek Headwaters, Pike County, Pennsylvania,
W86-00636 5B

CHEMICAL COMPOSITION
Chemical Composition of Highway Drainage Waters; I. Major Ions and Selected Trace Metals,
W86-00708 5B

Chemical Composition of River Sediments from the Indian Sub-Continent,
W86-00771 2J

CHEMICAL SPECIATION
Chemical Composition of Highway Drainage Waters; III. Runoff Water Metal Speciation Characteristics,
W86-00710 5B

CHEMISTRY OF PRECIPITATION
Analysis of Precipitation Chemistry Data from Alaska,
W86-00659 2K

Effects of Storage on the Composition of Main Components in Rainwater Samples,
W86-00717 2K

Chemical Components in the Precipitation at Komoro and Tsukuba, Japan in 1983,
W86-00810 5B

CHEMOTAXIS
Effects of Cadmium and Copper on Chemotaxis of Marine and Freshwater Ciliates,
W86-00696 5C

CHESAPEAKE BAY
Historical Changes in Submerged Macrophyte Communities of Upper Chesapeake Bay,
W86-00828 2H

CHICAGO
What's Going on Under Chicago,
W86-00767 8A

CHINA (PEOPLES REPUBLIC)
Freshwater Aquaculture in China: Ecosystem Management for Survival,
W86-00664 2H

Hydrogeological Prospecting Group and Types of Mineral Deposits Filled with Karst Water in China (in Chinese).
W86-00897 2F

CHLORINATED HYDROCARBONS
Organochlorine Residues in Animals from Three Louisiana Watersheds in 1978 and 1979,
W86-00691 5B

Occurrence of Chlorinated Polynuclear Aromatic Hydrocarbons in Tap Water,
W86-00895 5B

CHLORINATED PHENOLS
Extraction and Enrichment of Chlorinated Phenols from Surface Waters for the Determination by Capillary-GC/FTIR-Spectroscopy,
W86-00824 5A

CHLORINE
Extent of Monochloramine Interference in the DPD Colorimetric Method for Free Chlorine in Water,
W86-00833 5A

CHLOROPHYLL
Comparison of the Phosphorus-Chlorophyll Relationships in Mixed and Stratified Lakes,
W86-00614 2H

Seasonal Cycles of Phytoplankton Populations and Total Chlorophyll of the Lower St. Johns River Estuary, Florida,
W86-00900 2L

CHROMATOGRAPHY
Ion Chromatograph Provides Rapid Analysis of Air and Water,
W86-00768 5A

CIRCLE QUADRANGLE
Gold-Mining Effects on Stream Hydrology and Water Quality, Circle Quadrangle, Alaska,

STATISTICAL MODELS
Statistical Model for Conversion of Absorbance Measurements with Significant Iron Interference into Organic Carbon in a Polyhumic Lake,
W86-00676 5A

STEADY STATE MEASUREMENT
Steady State Measurement of Oxygenation Capacity,
W86-00756 5D

STEP-DRAWDOWN TESTS
Step-Drawdown and Constant-Rate Pumping Tests,
W86-00712 2F

STOCHASTIC HYDROLOGY
Stochastic Flood Analysis in a Region of Mixed Generating Processes,
W86-00646 2E

STOMACHS
Evidence for Polynuclear Aromatic Hydrocarbons in the Diet of Bottom-Feeding Fish,
W86-00694 5B

STORM DRAINS
Developing an Effective Storm Drainage Maintenance Program,
W86-00806 4A

STORM RUNOFF
Storm Water Runoff from Industrial Sites,
W86-00766 5B

Proportional Weirs for Stormwater Pond Outlets,
W86-00887 8A

STRATIFIED LAKES
Comparison of the Phosphorus-Chlorophyll Relationships in Mixed and Stratified Lakes,
W86-00614 2H

STREAM BIOTA
Evaluation by Field Experiments of the McLay Model of Stream Drift,
W86-00628 2H

STREAM POLLUTION
Gold-Mining Effects on Heavy Metals in Streams, Circle Quadrangle, Alaska,
W86-00786 5C

STREAMS
Model of Sulphate Concentration in a Small Stream in the Harp Lake Catchment, Ontario,
W86-00629 5B

Factors Controlling Mass Loss and Nitrogen Dynamics of Plant Litter Decaying in Northern Streams,
W86-00637 2K

Environmental Audit. II. Application to Stream Network Design,
W86-00723 7A

Use of Watershed Characteristics to Select Control Streams for Estimating Effects of Metal Mining Wastes on Extensively Disturbed Streams,
W86-00725 5C

Flowing Water Resources,
W86-00791 2A

Distribution and Persistence of Aminocarb in Stream Water, Sediment and Fish After Application of Three Matacil Formulations,
W86-00811 5B

STRUCTURED MODELLING
Structured Modeling of the Anaerobic Digestion of Biomass Particulates,
W86-00848 5D

SULFATES
Model of Sulphate Concentration in a Small Stream in the Harp Lake Catchment, Ontario,
W86-00629 5B

Sulfate Determination in Industrial Wastewater by Liquid Chromatography with Postcolumn Solid-Phase Reaction Detection,
W86-00819 5A

SULFIDES
Oxidation of Sulfide and Thiosulfate and Storage of Sulfur Granules in Thiothrix from Activated Sludge,
W86-00745 5D

Kinetic Studies of the Microbiological Conversion of Sulphate to Hydrogen Sulphide and Their Relevance to Sulphide Generation Within Sewers,
W86-00746 5D

SULFITES
Effect of Sulfite Dechlorination on the Accumulation of Waterborne Lead by Rainbow Trout (Salmo gairdneri),
W86-00615 5A

SULFUR
Oxidation of Sulfide and Thiosulfate and Storage of Sulfur Granules in Thiothrix from Activated Sludge,
W86-00745 5D

SULFUR BACTERIA
Kinetic Studies of the Microbiological Conversion of Sulphate to Hydrogen Sulphide and Their Relevance to Sulphide Generation Within Sewers,
W86-00746 5D

SULFUR DIOXIDE
Effect of Flooding of Soil on Growth and Subsequent Responses of Taxodium distichum Seedlings to SO2,
W86-00861 5C

SURGES
Simple Governing and Surging Simulation, Part One,
W86-00801 8B

SUSPENDED PARTICULATES
Bacterial Adsorption and Suspended Particles in Urban Stormwater,
W86-00842 5B

SUSPENDED SEDIMENTS
Statistical Determination of the Optimal Sample Size of Secondary Effluent BOD5 and SS,
W86-00683 5A

Chemical Composition of Highway Drainage Waters; II. Chemical Associations of Metals in the Suspended Sediment,
W86-00709 5B

SUSQUEHANNA RIVER
Additions to Ichthyofauna of the Susquehanna River with a Checklist of Fishes of the Susquehanna River Drainage below Conowingo Dam,
W86-00635 2H

SWALE
Environmental Impact of Paper Mill Waste Discharges to the Swale,
W86-00863 5C

SWEDEN
Allium Test on River Water from Braan and Saxan Before and After Closure of a Chemical Factory,
W86-00667 5A

SWIRL CONCENTRATORS
Use of a Swirl Concentrator for Combined Sewer Overflow Management,
W86-00844 5D

SWITZERLAND
Oligochaete Communities of the Sublittoral as Indicators of Lake Geneva Eutrophication,
W86-00624 5A

TACOMA
Removing VOC from Groundwater, [illegible] Scale-up, and Operating Experience,
W86-00816

TAILWATERS
Invertebrate Colonization Rates in the Ta[illegible] of a Kentucky Flood-Control Reservoir,
W86-00618

TANTARE LAKE
Zinc Deposition in Acid Lakes: The [illegible] Diffusion,
W86-00689

TEMPERATURE EFFECTS
Effect of Temperature on Oxygen Transf[illegible] in Wastewater Treatment,
W86-00658

Evaluation of Temperature Effects on T[illegible] Filter Plant Performance,
W86-00737

TENNESSEE
Phosphorus Spiralling in a Woodland S[illegible] Seasonal Variations,
W86-00830

TENNESSEE RIVER
Checklist of Phytoplankton (Exclusive o[illegible] toms) in Kentucky Reservoir,
W86-00631

TERRAIN ANALYSIS
Bottomland Vegetation Distribution Alon[illegible] sage Creek, Virginia, In Relation to [illegible] Landforms,
W86-00826

TESTING PROCEDURES
Method for Aquatic Multiple Species Te[illegible] Testing: Acute Toxicity of 10 Chemical[illegible] Vertebrates and 2 Invertebrates,
W86-00654

TETRAHYMENA
Testing for the Toxicity of Chemicals wi[illegible] trahymena pyriformis,
W86-00711

THAMES RIVER
Bulk Supply Scheme of the Mid Southe[illegible] North Surrey Water Companies,
W86-00835

THERMAL POLLUTION
Replacement of Stenonema spp. by Cae[illegible] minuta Walker as the Numerical Domin[illegible] the Mayfly Assemblage of a Thermally-S[illegible] Stream,
W86-00617

THERMOPHILIC DIGESTION
Thermophilic Anaerobic Contact Digest[illegible] Palm Oil Mill Effluent,
W86-00744

THIOSULFATES
Oxidation of Sulfide and Thiosulfate and S[illegible] of Sulfur Granules in Thiothrix from Ac[illegible] Sludge,
W86-00745

THIOTHRIX
Oxidation of Sulfide and Thiosulfate and S[illegible] of Sulfur Granules in Thiothrix from Ac[illegible] Sludge,
W86-00745

THIRAM
Example of Interaction Between Environ[illegible] Pollutants: Modification of Thiram Toxi[illegible] Freshwater Organisms by Nitrites or Nitr[illegible] Relation to Nitrosamine Synthesis,
W86-00877

ical Impact of Mining in a Th-Rich
an Area,

SELECTED WATER RESOURCES ABSTRACTS

DEPOSITORY
APR 3 1986
UNIVERSITY OF ILLINOIS
AT URBANA-CHAMPAIGN

VOLUME 19, NUMBER 4
APRIL 1986

86-01319
ABW

SELECTED WATER RESOURCES ABSTRACTS (SWRA) is produced by the Geological Survey, U.S. Department of the Interior, and published monthly by the National Technical Information Service (NTIS), U.S. Department of Commerce.

SWRA is available to Federal agencies and their contractors or grantees in water resources research upon request, citing contract or grant number and sponsoring agency. Write: Water Resources Division, U.S. Geological Survey, MS 425, Reston, VA 22092. The **SWRA Journal** is also available on subscription from NTIS, 5285 Port Royal Road, Springfield, VA 22161. Annual subscription rates for the North American Continent are: Journal only, $115, Journal and Annual Indexes, $145; Indexes only, $50. Other addressees, write for prices.

Some documents abstracted in this journal can be purchased from NTIS. Price codes are given in the entries and a current code-price conversion table is printed on the outside back cover. Other documents are available from originating organizations or authors as indicated in the citation.

SELECTED WATER RESOURCES ABSTRACTS

A monthly publication of the Geological Survey
U.S. Department of the Interior

VOLUME 19, NUMBER 4
APRIL 1986

W86-00920 -- W86-01319

The Secretary of the Interior has determined that the publication of the periodical is necessary in the transaction of the public business required by law of this Department.

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

PREFACE

S elected Water Resources Abstracts, a monthly journal, includes abstracts of current and earlier rtinent monographs, journal articles, reports, and ner publication formats. These documents cover ter resources as treated in the life, physical, and cial sciences and the related engineering and legal pects of the characteristics, supply condition, con-rvation, control, use, or management of water ources. Each abstract includes a full bibliographic ation and a set of descriptors which are listed in **Water Resources Thesaurus.** The abstract ries are classified into 10 fields and 60 groups ilar to the water resources research categories ablished by the Committee on Water Resources search of the then Federal Council for Science and hnology.

ected Water Resources Abstracts is designed erve the scientific and technical information needs scientists, engineers, and managers as one of several services of the Water Resources Scientific Information Center. The cumulative SWRA file from 1968 and monthly updates are available also in magnetic tape through lease from NTIS.

THE WATER RESOURCES SCIENTIFIC INFORMATION CENTER DOES NOT PROVIDE COPIES OF DOCUMENTS ABSTRACTED IN THIS JOURNAL. Sufficient bibliographic information is given to enable readers to order the desired documents from local libraries or other sources.

Comments and suggestions concerning the contents and arrangement of this bulletin are welcome.

CONTENTS

SUBJECT FIELDS AND GROUPS

Please use the edge index on the back cover to locate Subject Fields and Indexes.

01 NATURE OF WATER

Includes the following Groups: Properties; Aqueous Solutions and Suspensions.

02 WATER CYCLE

Includes the following Groups: General; Precipitation; Snow, Ice, and Frost; Evaporation and Transpira Streamflow and Runoff; Groundwater; Water in Soils; Lakes; Water in Plants; Erosion and Sedimenta Chemical Processes; Estuaries.

03 WATER SUPPLY AUGMENTATION AND CONSERVATION

Includes the following Groups: Saline Water Conversion; Water Yield Improvement; Use of Water of Impa Quality; Conservation in Domestic and Municipal Use; Conservation in Industry; Conservation in Agricul

04 WATER QUANTITY MANAGEMENT AND CONTROL

Includes the following Groups: Control of Water on the Surface; Groundwater Management; Effects on Wa Man's Nonwater Activities; Watershed Protection.

05 WATER QUALITY MANAGEMENT AND PROTECTION

Includes the following Groups: Identification of Pollutants; Sources of Pollution; Effects of Pollution; W Treatment Processes; Ultimate Disposal of Wastes; Water Treatment and Quality Alteration; Water Q Control.

06 WATER RESOURCES PLANNING

Includes the following Groups: Techniques of Planning; Evaluation Process; Cost Allocation, Cost Sha Pricing/Repayment; Water Demand; Water Law and Institutions; Nonstructural Alternatives; Ecologic Impa Water Development.

07 RESOURCES DATA

Includes the following Groups: Network Design; Data Acquisition; Evaluation, Processing and Publicati

08 ENGINEERING WORKS

Includes the following Groups: Structures; Hydraulics; Hydraulic Machinery; Soil Mechanics; Rock Mech and Geology; Concrete; Materials; Rapid Excavation; Fisheries Engineering.

09 MANPOWER, GRANTS, AND FACILITIES

Includes the following Groups: Education—Extramural; Education—In-House; Research Facilities; Gr Contracts, and Research Act Allotments.

10 SCIENTIFIC AND TECHNICAL INFORMATION

Includes the following Groups: Acquisition and Processing; Reference and Retrieval; Secondary Public and Distribution; Specialized Information Center Services; Translations; Preparation of Reviews.

CONTINUOUS CONVOLUTION WITH HYDROLOGIC DATA,
New South Wales Univ., Kensington (Australia). School of Civil Engineering.
T. G. Chapman.
Water Resources Research, Vol. 21, No. 6, p 847-852, June, 1985. 5 Fig, 3 Tab, 7 Ref.

Descriptors: *Hydrologic data, *Convolution equation, Sampling, Algorithms, Mathematical equations, Deconvolution.

The integral form of the convolution equation can be used for hydrologic data sampled at equal time increments of simple functional forms are assumed for the change in the hydrologic variables between sampling points. The forms studied here are a step function, linear segment, and sliding polynomial, and algorithms are presented for convolution of all combinations of these functions. The effect of the different assumptions is demonstrated by a sample data set. These algorithms have three advantages: an appropriate functional form can be selected for the two variables to be convolved, different time increments may be use for the two variables, and the output may be calculated at any point in continuous time, not just at multiples of the sampling increments. The algorithms may also be applied to deconvolution but suffer many of the difficulties of matrix inversion techniques when the data contain errors or are derived from a system which is only approximately linear. STOCHASTIC MODELS APPLIED TO EVALUATING HYDROLOGIC CHANGES,
National Council for Scientific Research, Lusaka (Zambia). Water Resources Research Unit.
T. C. Sharma.
Journal of Hydrology, Vol. 78, No. 1/2, p 61-81, May, 1985. 6 Fig, 6 Ref, 13 Ref.

Descriptors: *Model studies, *Hydrologic models, *Kafue River basin, *Zambia, *Rainfall-runoff relationships, Runoff, Temporal distribution, History, Discharge.

Simple statistical tests for equality of means and variances, and Box-Jenkins univariate and input-output models were applied to the Kafue River Basin, Zambia, to detect hydrologic changes. The structural decomposition of monthly runoff series into periodic and stochastic components, and the step response function of monthly runoff processes in relation to monthly rainfall processes provide parameters that form a basis for evaluating the changes in the hydrologic environments. The hydrologic changes were found to be reflecting changes of the model parameters in the following manner: (1) The steady-state or the equilibrium value for the rainfall-runoff step response function rose after the mid-1930's, suggesting that the potential of the basin increased for generating the runoff water. (2) The time constant (months) for the monthly rainfall-runoff system increased after the mid-1930's, suggesting that the transmission capability of the system for transporting the generated runoff tended to slow down during the same period. (3) The role of the stochastic component in influencing the monthly runoff process grew after the mid-1930's. The stochastic component behaved as a Markov or AR(1) process before the mid 1930's, while the behavior of the stochastic component resembled an ARMA(1,1) process after that. (4) The levels of yearly and monthly runoff depths (discharges), yearly maximum daily discharges and yearly minimum daily discharges underwent a general rise after the mid-1930's. (Author's abstract)

HIGHEST OBSERVED 1 TO 10-DAY POINT AND AREAL RAINFALL OVER KERALA STATE,
Indian Inst. of Tropical Meteorology, Poona.
S. A. Saseendran, P. R. Rakhecha, and O. N. Dhar.
Indian Journal of Power and River Valley Development, Vol. 33, No. 12, p 438-443, December, 1983. 10 Fig, 4 Tab, 5 Ref.

Descriptors: *Rainfall, *Kerala, *India, Rainfall area, Rainfall distribution, Altitude.

Daily rainfall data of about 100 stations in and around Kerala State (India) for a period of 70 years from 1901-1970 have been analyzed to determine the the highest rainfall amounts for 1 to 10-day durations. Using the highest rainfall data at each of 100 stations a family of generalized highest rainfall charts of 1 to 10-day durations were prepared. The highest 1-day rainfall values range from 21 to 53 cm. Heavy falls of rain of 40 cm or more in one day are confined to areas close to the Western Ghats on their windward sides. The 2-day highest rainfall varies from 31-85 cm. The highest point rainfall values for 10-day rainfall ranged from 62-243 cm. A common feature revealed by all the maps is that high rainfall values occur over and near the Western Ghats and isolines of rainfall almost run parallel to the contour lines. Vayittiri station recorded the highest rainfall amounts for all 10 durations. At the rainiest stations about 30% of the maximum rainfall in a 10-day duration is recorded in one day and about 40-50% in 2 day duration. (Moore-IVI)

RECENT CHANGES IN SUMMER RAINFALL VALUES MEASURED AT LONG ASHTON,
Bristol Weather Center (England).
M. R. Woodley.
Weather, Vol. 40, No. 6, p 180-183, June, 1985. 5 Fig, 1 Tab.

Descriptors: *Seasonal variation, *Rainfall, *England, *Long Ashton, Drought, Water supply.

Changes in summer rainfall amounts in one part of the south-west of England are documented. Differences between the 1984 dry spell and the one in 1975-76 are also noted. Analysis of annual rainfall totals considered as a 25 year running mean shows an irregular decline from 1944 until 1979, after which all but one of the following years had above average rainfall. Even so, over the period as a whole, this represents a decline of about 52 mm in average annual values, using linear regression. For the period 1972-78 when the rate of change was at its greatest, the decrease was significant at the one percent level. A decrease in rainfall is noted in the mid-1970s, with its nadir in August 1976, and another very low point in November 1978. Thereafter, monthly rainfall amounts were frequently above average so that the cumulative difference from the 30-year average had returned to near zero by January 1983. Seasonal rainfall for the summer months shows an altogether different pattern. During 1971-84 there were four very dry summers and only one very wet summer. In the 13 year period from 1979-84 there were only three summers with above average rainfall. Put against the changes in annual rainfall values it becomes clear that the present dry spells are set against above-average rainfall in the preceding four or five years, whereas the drought of the mid-1970s was part of a continuing decline in annual rainfall. (Baker-IVI)

2C. Snow, Ice, and Frost

MACHINE CLASSIFICATION OF FRESHWATER ICE TYPES FROM LANDSAT-1 DIGITAL DATA USING ICE ALBEDOS AS TRAINING SETS,
National Oceanic and Atmospheric Administration, Ann Arbor, MI. Great Lakes Environmental Research Lab.
G. A. Leshkevich.
Remote Sensing of Environment, Vol. 17, No. 3, p 251-263, June, 1985. 5 Fig, 1 Tab, 38 Ref.

Descriptors: *Ice, *Albedo, *Landsat-1, *Remote sensing, *Green Bay, *Great Lakes, *Lake Michigan, Satellite technology, Reflectance, Lake ice.

A method has been used to convert ground-measured freshwater ice albedos to Landsat-1 digital numbers indirectly corrected for atmospheric attenuation and path radiance. The method has been tested by using the digital numbers as training sets to machine classify Landsat-1 digital ice cover data from a portion of northern Green Bay (Lake Michigan) imaged on 13 February 1975. The conversion algorithm produced digital numbers that, when used as training sets, classified approximately 50% of the test area. Differences between the classified test area and a previous machine classification of the scene, as well as the percentage of unclassified area caused by lack of data for some surface types, points to the need for a more comprehensive, well-documented library of signatures representing Great Lakes ice types. (Author's abstract)

2D. Evaporation and Transpiration

EVAPOTRANSPIRATION DERIVED FROM SATELLITE OBSERVED SURFACE TEMPERATURES,
Utrecht Rijksuniversiteit (Netherlands). Inst. voor Meteorologie en Oceanografie.
W. Klaassen, and W. van Den Berg.
Journal of Climate and Applied Meteorology, Vol. 24, No. 5, p 412-424, May, 1985. 17 Fig, 1 Tab, 38 Ref.

Descriptors: *Evapotranspiration, *Satellite technology, *Remote sensing, *Soil temperature, *Surface temperatures, Energy balance method, Wind velocity, Air temperature, Model studies.

Evapotranspiration was calculated from surface temperatures using an energy balance method. This method is sensitive to the temperature difference between the surface and the air above, and somewhat to the windspeed. The influence of the spatial variability of air temperature on the interpretation of surface temperatures was considered. Small-scale atmospheric variations can be corrected by using temperature and wind data at a height of 50 m. Three models have been used to calculate these 50 m data from standard weather observations. The first model uses a very simple concept of constant temperature and wind over the test area (zero-dimensional). In the second model windspeed is also taken constant, but air temperature is evaluated from the initial vertical temperature in the atmosphere with a one-dimensional slab layer model. The third model is a two-dimensional primitive equations model in which wind velocity is calculated from the geostrophic wind and air temperature similar to model 2. A homogeneous grassland area was selected in the north of the Netherlands close to the sea. Several days in the summer of 1983 with clear skies and winds from the sea were selected. Surface temperatures were derived from the NOAA-7 satellite overpass in the early afternoon using the split-window technique. On most days an almost linear increase of both surface and air temperature is found with increasing distance to the sea. This study reveals that 1 results in an unrealistic decrease of the calculated evapotranspiration with increasing distance to the coast. Furthermore evapotranspiration is underestimated. The evapotranspiration as calculated with models 2 and 3 is almost constant in the test area and agrees well with measurement. Model 3 gave more scatter, probably due to the fact that uncalibrated wind velocities were used. For practical calculation of evapotranspiration the Priestley-Taylor parameter 'alpha' is often used. This study shows how this parameter can be derived from satellite observations of surface temperature. (Author's abstract)
W86-01135

STOMATAL RESPONSES AND WATER RELATIONS OF EUCALYPTUS PAUCIFLORA IN SUMMER ALONG AN ELEVATIONAL GRADIENT,
Innsbruck Univ. (Austria). Botanisches Inst.
C. Korner, and P. M. Cochrane.
Oecologia, Vol. 66, No. 3, p 443-455, June, 1985. 12 Fig, 8 Tab, 68 Ref.

Descriptors: *Plant physiology, *Stomata, *Eucalyptus, *Australia, *Snowy Mountains, *Leaves, *Leaf conductance, *Trees, Plant water potential, Water potentials, Altitude, Elevation, Preciptation, Evaporation, Humidity, Soil water, Water balance.

The spatial and temporal variation of leaf conductance (g) in Eucalyptus pauciflora was analyzed with respect to photon flux area density (I), temperature (T), water vapor concentration deficit (Delta w), and leaf water potential (Psi) at four different sites between 940 m and 2,040 m altitude in the Snowy Mountains of south-eastern Australia. Along this altitudinal gradient the precipitation/evaporation ratio increases from 1 to 4. The results show that gas diffusion in this tree species is primarily controlled by I and Delta w at all sites, independently of the specific soil moisture regimen. Even under dry midsummer conditions with predawn leaf water potentials of - 1 MPa at the lowest altitude, Psi had no striking effect on g. The humidity threshold for the onset of stomatal closure does not vary greatly between the study sites (12.2 + or - 1.3 Pa/kPa). The highest and lowest values observed for Psi, the osmotic potential at water saturation (from pressure/volume curves), the mean and maximum g and stomatal density, all increase with elevation. The highest (least negative) osmotic potentials were obtained at all sites in midsummer. It therefore appears that there is no osmotic adjustment to drought in the seasonal course. The maximum difference between osmotic potentials obtained at the lowest and highest sites is 0.46 MPa. In general osmotic potential varies less than has been reported for other plant species exposed to varying water regimens. This may be the consequence of the pronounced feed-forward response of the stomata to evaporative demand, which led to only moderate tissue desiccation, never exceeding the turgor loss point. E. pauciflora is a tree species with a very conservative utilization of soil water, which adjusts to drought via stomatal control of water loss, rather than via osmotic properties. These results explain previous reports of the comparatively high susceptibility of E. pauciflora to severe drought and its positive influence on the hydrological balance of mountain ecosystems in the Australian Alps. (Author's abstract)
W86-01163

2E. Streamflow and Runoff

NEGATIVE OUTFLOWS FROM MUSKINGUM FLOOD ROUTING,
Agricultural Research Service, Columbia, MO. North Central Watershed Research Unit.
A. T. Hjelmfelt, Jr.
Journal of Hydraulic Engineering, Vol. 111, No. 6, p 1010-1014, June, 1985. 15 Ref.

Descriptors: *Muskingum Flood Routing, *Flood routing, *Flood control, Floods, Mathematical equations.

The Muskingum flood routing equation was treated as a difference form of a discrete linear response function. The response function, which represents the routine of a unit impulse through the system, was investigated to determine the criterion for ensuring only positive ordinantes. Realistic inflow sequences may be routed with less severe restrictions and still have only positive outfl
criterion will depend upon the inflo
Practical application of the Muskingu
will seldom yield negative ordinates.

Descriptors: *Meandering streams, *Unstable channels, *River beds, *Secondary currents, Water currents, Stream beds, Channel erosion, Channeling, Hydraulics.

Natural channels often adopt a meandering course. Water flow in meander bends is three-dimensional, consisting of primary velocities which are tangential to the bend, and secondary velocities, which are in the radial plane. The pattern of secondary flow strongly affects the distribution of primary velocities. This in turn affects the distribution of erosion and deposition in the bend and the way in which the channel shifts and changes shape. Measurements of primary and secondary flows in a meandering gravel-bed river show that, in addition to the widely recognized main secondary circulation driving surface water outwards and bed water inwards, there can be a small cell of reverse rotation at the outer bank. Further data have been collected in a sand-bedded river at low, intermediate and high discharges. The results confirm the existence of the main and outer bank cells but also indicate that in some bends the main cell does not extend to the inner bank. In fact, secondary flow at the inner bank of wide, shallow bends is directed radially outwards over the whole flow depth at all in-channel flows. This indicates that some models of bend flow and channel development may be significantly in error. (Author's abstract)

COVARIANCE BETWEEN SUBSAMPLE MEAN AND VARIANCE AS RELATED TO STORAGE VARIABLES,
Technical Univ. of Istanbul (Turkey). Dept. of Civil Engineering.
M. Bayazit, J. T. B. Obeysekera, and V. Yevjevich.
Journal of Hydrology, Vol. 78, No. 1/2, p 137-150, May, 1985. 9 Fig, 8 Ref.

Descriptors: *Covariance, *Hydrologic modeling, *Flow, *Statistical analysis, *Storage, Model studies, Data interpretation, Seasonal variation, Flow regulation.

The covariance between mean and variance of subsamples was conceived as a single parameter which integrates the effects of asymmetrical extremes and dependence structure on storage capacity required for seasonal flow regulation. An exact expression for this covariance for the first-order autoregressive processes was derived. The use of covariance for estimation of skewness was investigated by simulation for both independent and dependent stationary processes. This approach results in a lesser bias in estimated skewness than the moment estimator. The relationship between covariance and the storage related variables, such as range and deficit, was studied by simulation. Covariance was positively correlated with mean range and deficit for skewness smaller than 3, and negatively correlated with adjusted range. These storage related variables are influenced in different ways by the sampling fluctuations in the coefficients of skewness and serial correlation. (Author's abstract)

RADIOCARBON DATING OF GROUNDWATER IN TERTIARY SEDIMENTS OF THE EASTERN MURRAY BASIN,
Water Resources Commission of New South Wales, Sydney (Australia).
L. W. Drury, G. E. Calf, and J. K. Dharmasiri.
Australian Journal of Soil Research, Vol. 22, No. 4, p 379-387, 1984. 4 Fig, 3 Tab, 10 Ref.

Descriptors: *Carbon radioisotopes, *Groundwater, *Murray Basin, *New South Wales, Geohydrology, Groundwater recharge, Groundwater movement, Radioactive dating.

The Tertiary sediments located in the eastern part of the Murray Basin contain one of the most important low salinity groundwater resources in New South Wales. This has been especially apparent during recent years as increasing demands on the resource are being made by irrigators and municipal water suppliers. It is therefore imperative that the hydrogeological environment in which the groundwater occurs by thoroughly understood to allow adequate management of the resource. As part of a systematic exploration of the Tertiary aquifer systems, the Australian Atomic Energy Commission, in association with the Water Resources Commission of New South Wales, carried out a radiocarbon dating project on 37 groundwater samples from bores screened in these unconsolidated sediments. The results indicate water ages in the ranges 'modern' to 15,800 years. Groundwater recharge areas are indicated and rates of groundwater recharge and movement determined. The latter shows close correlation with velocity values quantitatively determined by Darcy's law. (Author's abstract)

UNSATURATED AND SATURATED FLOW THROUGH A THIN POROUS LAYER ON A HILLSLOPE,
Western Australia Univ., Nedlands. Dept. of Mathematics.
D. G. Hurley, and G. Pantelis.
Water Resources Research, Vol. 21, No. 6, p 821-824, June, 1985. 3 Fig, 10 Ref.

Descriptors: *Unsaturated flow, *Saturated flow, *Storm seepage, *Slopes, Porous media, Infiltration, Kinematic wave theory, Water table, Mathematical equations, Hills.

The subsurface stormflow in a layer of porous earth overlying an impervious hill is investigated in

the case when the thickness of the layer is small compared to a typical hill dimension. If the infiltration rate at the surface is low and varies slowly with time, the head is approximately constant along normals to the hillslope, and the flow in both the saturated and unsaturated regions is described by a simple kinematic wave equation. Solutions of this equation describe the spatial and temporal development of the water table as well as the flow in the saturated and unsaturated regions. A numerical example is given. COMPARISON OF GAUSSIAN CONDITIONAL MEAN AND KRIGING ESTIMATION IN THE GEOSTATISTICAL SOLUTION OF THE INVERSE PROBLEM,
Calvin Coll., Grand MI. Dept. of Engineering.
R. J. Hoeksema, and P. K. Kitanidis.
Water Resources Research, Vol. 21, No. 6, p 825-836, June, 1985. 19 Fig, 1 Tab, 11 Ref, 1 Append.

Descriptors: *Geohydrology, *Geostatistical methods, *Mathematical models, *Kriging, *Inverse problem, Transmissivity, Hydraulic head, Aquifers, Pumping, Groundwater.

Two separate applications of the geostatistical solution to the inverse problem in groundwater modeling are presented. Both applications estimate the transmissivity field for a two-dimensional model of a confined aquifer under steady flow conditions. The estimates are based on point observations of transmissivity and hydraulic head and also on a model of the aquifer which includes prescribed head boundaries, leakage, and steady state pumping. The model used to describe the spatial variability of the log-transmissivity describes large-scale fluctuations through a linear mean or drift intermediate and small-scale fluctuations through a two-parameter covariance function. The first application presented estimates the log-transmissivities using Gaussian conditonal mean estimation. The second application uses extended form of cokriging. The two methods are compared and their relative merits discussed. The extended cokriging application is applied to the Jordan Aquifer of Iowa. A comparison is also made between the conditional mean application and an analytical approach. (Author's abstract)

VARIANCE REDUCTION ANALYSIS,
Georgia Inst. of Tech., Atlanta. School of Civil Engineering.
S. Rouhani.
Water Resources Research, Vol. 21, No. 6, p 837-846, June, 1985. 4 Fig, 2 Tab, 37 Ref.

Descriptors: *Variance reduction analysis, *Sampling, *Algorithms, Groundwater, Costs, Planning, Network design.

An attempt is made to develop a data collection algorithm, known as the variance reduction analysis. The proposed method is based on an information response function (i.e., the amount of information gain at an arbitrary point due to a measurement at another site. This method was later applied to groundwater data management problems. Total variance reduction (a measure for the information gain) which is independent of measured values was used as a tool for the design and planning of such data collection schemes. By utilizing a loss function, planners can estimate monetary values of the added data. By assuming that measurement fluctuations are normally distributed, a two-piece linear loss function yielded an expected loss that was directly proportional to the square root of the kriging variance. The two indicators of information and economic gains led to an optimal sampling scheme. Based on the information gain function, selected points were ranked as prospective new sampling sites. Using the economic gain function, the optimal number of added points was calculated as a function of cost-loss ratio. The selected sequence of sites for further sampling shows a high degree of stability with respect to noisy inputs. The variance reduction analysis is an effective algorithm for the planning and design of data collection schemes in random fields. (Moore-IVI)

QUANTITATIVE ANALYSIS OF THE LASSEN HYDROTHERMAL SYSTEM, NORTH CENTRAL CALIFORNIA,
Geological Survey, Menlo Park, CA.
S. E. Ingebritsen, and M. L. Sorey.
Water Resources Research, Vol. 21, No. 6, p 853-868, June, 1985. 14 Fig, 2 Tab, 26 Ref.

Descriptors: *Lassen Volcanic National Park, *California, *Geothermal resources, Hydrothermal studies, Chlorides, Steam, Mathematical models, Simulation, Groundwater movement.

This conceptual model of the Lassen system is termed a liquid-dominated hydrothermal system with a parasitic vapor-dominated zone. The essential feature of this model is that steam and steam-heated discharge at relatively high altitudes in Lassen Volcanic National Park (LVNP) and liquid discharge with chloride concentrations at relatively low altitudes outside LVNP are both fed by an upflow of high-enthalpy two-phase fluid within the Park. Liquid flows laterally away from the upflow area toward the areas of high-chloride discharge, and steam rises through a vapor-dominated zone to feed the steam and steam-heated features. Numerical simulations show that several conditions are necessary for the development of this type of system, including (1) large-scale topographic relief; (2) an initial period of convective heating within an upflow zone followed by (3) a change in hydrologic or geologic conditions that initiates drainage of liquid from portions of the upflow zone; and (4) low-permeability barriers that inhibit the movement of cold water into the vapor zone. Simulations of thermal fluid withdrawal south of LVNP, carried out in order to determine the effects of such withdrawal on portions of the hydrothermal system within the Park, generally showed decreases in pressure and liquid saturation beneath the vapor zone which resulted in temporary increases and subsequent decreases in the rate of upflow of steam. A generalized production-injection scenario that could mitigate the effects of development on both the high-chloride and steam-fed features was identified. (Author's abstract)

Water Resources Research, Vol. 21, No. 6, p 869-883, June, 1985. 11 Fig, 5 Tab, 27 Ref. MAF grants CEE 81-13500 and CEE 83-01230.

Descriptors: *Groundwater, *Inverse problem, *Parameter structure, *Model studies, Optimization, Mathematical studies.

This paper develops an optimization method that can be used to identify parameter structure as well as its values in connection with the inverse problem in groundwater modeling. The complexity of the parameter structure is determined by the quantity and quality of observation data. Output least square error is used as the criterion of identification. Sensitivity coefficients at finite element nodes are evaluated by the variational method. The problem of identifying the parameter structure is formulated as a problem of combinatorial optimization. A new parameterization technique is presented for describing the parameter structure. It can represent various distributions of parameters from piecewise constant to continuous variability. Based on this representation, the combinatorial optimization problem for determining the parameter structure is then solved by a simple one-at-a-time searching procedure. Numerical experimentations are used to demonstrate the efficiency and practicality of the proposed method. (Author's abstract)

ative forest has caused a rise in soil and secondary salinization in south Western Australia. An experiment in reclamation began in May 1976 with the replanting of tree vegetation near salt seeps. Spectral analysis was used to relate the subsequent changes in static water levels of the groundwater to rainfall input and progressive leaf area index of two plantations on a single subcatchment. The upslope static water levels lagged the seasonal rainfall by 3-4 months, whereas the midslope levels lagged rainfall by approximately 1 month. Increasing leaf area of the plantations corresponded to decreasing groundwater levels in their vicinity. (Author's abstract)

FLOW IN A LIMESTONE AQUIFER AS DETERMINED FROM WATER TRACING AND WATER LEVELS IN WELLS,
Kentucky Univ., Lexington. Dept. of Geology.
J. Thrailkill.
Journal of Hydrology, Vol. 78, No. 1/2, p 123-136, May, 1985. 3 Fig, 29 Ref.

Descriptors: *Groundwater movement, *Aquifers, *Limestone, *Water level, *Tracers, *Wells, *Kentucky, *Karst hydrology, Geohydrology, Springs, Streams, Perched aquifers, Potentiometric level.

The Inner Bluegrass Karst Region of central Kentucky is a fluviokarst underlain by flat-lying slightly argillaceous limestones (Ordovician). Water tracing and field observations have shown the aquifer to be divisible into groundwater basins and intervening interbasin areas. Flow in groundwater basins is in a dendritic system of solution conduits at depths as great as 35 m beneath the surface which often passes beneath surface divides to emerge at low-level springs, in contrast to interbasin areas in which the flow is shallow and generally parallels surface slopes. The availability of relatively dense water-level data in an area in which a number of water traces had been conducted allowed a comparison between the configuration of the potentiometric surface and water tracing data. The potentiometric surface map was generally consistent with the location of groundwater basins and interbasin areas. In addition, water levels near streams were found to be controlled by the stream and a few wells indicated perched aquifers. The potentiometric surface, however, failed to show narrow groundwater basins and did not adequately indicate groundwater flow directions previously established by water tracing. Although well data may furnish valuable supplemental information, water tracing is necessary to determine adequately subsurface flow directions in the region and in similar karst aquifers elsewhere. Descriptors: *Water quality, *Aquifers, *Groundwater contamination, *Pumping wells, *Mexico, Water temperature, Conductivity, Wells, Water sampling.

An analysis of the water flow under pumping stress in simple stratified aquifers, and field measurements of water quality from three sites in Mexico demonstrate the kind of information that can be obtained by observing water-quality changes (temperature and electrical conductivity) with time in a pumped well. Both short-term (hours) and longterm (years) changes were recorded. Water-quality changes provide information on the water quality near and far from the pumping well, and in some cases, the relative position within the aquifer of zones of different water quality. If changes in water quality are observed for different times after the well has been in production, then zonal changes in relative yield or quality may be detected. In the cases described in the paper, a representative sample of the aquifer in which the well is screened does not necessarily indicate the quality of water that will be produced over either the short or long term. In this case the term 'representative sample' is misleading. Short-term water-quality changes should be considered in setting operating parameters for optimal water quality. (Author's abstract)

DECREASE OF HYDRAULIC CONDUCTIVITY IN SAND AT THE INTERFACE BETWEEN SEAWATER AND DILUTE CLAY SUSPENSIONS,
Weizmann Inst. of Science, Rehovoth (Israel).
L. C. Goldenberg.
Journal of Hydrology, Vol. 78, No. 1/2, p 183-199, May, 1985. 5 Fig, 2 Tab, 44 Ref.

Descriptors: *Permeability coefficient, *Saline-freshwater interface, *Coastal aquifers, *Clay minerals, Aquifers, Seawater, Groundwater movement, Deflocculation, Sand.

The hydraulic conductivity of the seawater-fresh groundwater interface zone in coastal aquifers may decrease due to deflocculation and dispersion of small amounts of arrangements of reactive clay minerals that exist in the rock. This dispersed phase may influence to a large degree the connectivity between the conducting pores of a sediment. A reduction of hydraulic conductivity by 2-3 orders of magnitude was observed in analytically pure sand as well as in shore sand packed in columns when an interface between seawater and a dilute suspension of montmorillonite was created. The experiments were done by introducing suspensions of 5, 15, 30 and 60 mg/l of montmorillonite to columns in which a flow of seawater has previously been established. An amount of clay as small as 0.005% was involved in the creation of low permeability. The proposed model for explanation of the observed reduction of hydraulic conductivity assumes that at a certain stage the fluid begins to behave as a non-Newtonian fluid since loose networks of clay particles trap approximately 99% of water, causing stoppage in the 'bottlenecks' of the porous medium. As a consequence the overall sediment behaves as a 'Bingham system', with a yield stress. Coating of sand grains with clay is also assumed to occur in the case of concentrated suspension. ming, *Groundwater movement, Carbonates, Karst hydrology, Limestone, Permeability, Artesian basins, Hydraulic gradient.

Local steepening of hydraulic gradients dictate the locations where caves develop within a soluble rock sequence. An example of cave systems that fit this model are the extensive caves that have developed under canyons in the Trapper-Medicine Lodge recharge area where groundwater flow rates became maximized within the Madison carbonates during Cenozoic time. The Trapper-Medicine Lodge area is situated on the eastern perimeter of the Bighorn artesian basin, and serves as a recharge area for aquifers interbedded within the Paleozoic and Mesozoic section. The sediments dip gently westward at about six degrees in a homocline that is being stripped of its younger sediments by erosion. The large flow rates resulted directly from the superposition of steep local gradients on the groundwater circulation system as a consequence of the erosion of confining units in the region. Gradients within the Madison aquifer were steepest in the zones directly under and adjacent to the canyon floors. Today, average gradients in the Trapper-Medicine Lodge area are 400 ft/mi as compared to 40 ft/mi in the adjacent parts of the Bighorn basin. The permeabilities of the Madison aquifer at the time of exposure were small and were similar to those found in the unfaulted interior of the Bighorn basin. However, enhanced groundwater circulation rates through the carbonate rocks proximal to the canyons accelerated dissolution along joints in those zones. As this preferential circulation-dissolution process proceeded, caves began to develop and become highly localized under and adjacent to the entrenching canyon floors. This is exactly the condition that is found today, except caves observed today are the youngest in the system because older upper level networks have been eroded away as the canyons have deepened. The cave forming process in this area is gradient controlled, a conclusion that has possible applicability elsewhere. (Collier-IVI)

Descriptors: *Model studies, *Wells, *Groundwater flow, Water table, Permeability, Aquifer storage, Water storage, Aquifers, Chakpatni Test, Transmissivity.

A digital model is shown to successfully simulate the distribution of head in and around a large-diameter well during both the pumping and recovery phases. Existing methods of analysis are unsuitable for the case as described where the well partially penetrates a layered aquifer of low permeability. The weathered zone behaves as a layered aquifer. There is a time lag between an observable response in the water table and a decline in the head of the underlying, more permeable layer. After a dug well has been pumped in an aquifer of low permeability, the water level in the well rises while the cone of depression continues to expand, with a consequent fall in the water level around the well. The maximum radius of influence can be in excess of 50 m which may be reached several hours after pumping has stopped. This complex flow situation makes analysis by standard drawdown-time methods invalid. The dug well recovery rate is sensitive to the permeabilities of the fast layer but less sensitive to the aquifer storage coefficient and the permeability of the slow layer. The vertical component of ground water flow into a dug well can be important. The computed and observed water level recovery data for the dug well appears to lie as a straight line on a log-linear plot. This may be true only where the main producing zone is not dewatered and the transmissivity of the aquifer remains constant throughout the test. The Chakpatni test was modeled satisfactorily, and the computed aquifer parameters agree reasonably well with the result from a slug injection test. The hydraulic behavior of the dug well is now sufficiently well understood for investigation of optimum well design to be undertaken. (Baker-IVI)

SOME COMPUTATIONAL EXPERIENCES USING EMBEDDING TECHNIQUE FOR GROUND-WATER MANAGEMENT,
Nevada Univ., Reno. Dept. of Civil Engineering.
Y. K. Tung, and C. E. Koltermann.
Ground Water, Vol. 23, No. 4, p 455-464, July-August, 1985. 6 Fig, 18 Ref. Office of Water Research and Technology project A-103-NEV.

Descriptors: *Embedding techniques, *Groundwater management, *Model studies, *Las Vegas Valley aquifer, Hydraulic head, Pumpage, Groundwater movement.

A distributed parameter groundwater management model was developed using finite-difference approximations of the governing differential equation for groundwater flow in a confined aquifer. The resulting system of simultaneous equations was embedded in an optimization model, which used hydraulic heads and pumpages as unknown state variables and decision variables, respectively. The model was applied to several hypothetical examples of varying size and complexity and to one real-world example, the Las Vegas Valley aquifer. The grid spacing, time increment, bounds placed on pumpage, and the number of constraints were found to affect not only the execution time, but also whether the model would execute at all. In order to accommodate long-term management goals, a lumped transient model should be used which incorporates all time periods the model encompasses. Some objective functions, such as the maximization of the head, can be executed in a stepwise manner in which the final heads from the current period are used as the initial heads for the next period. The embedding technique proved useful for small management problems, but had numerical difficulties with the large real-world problems of considerable heterogeneity. Unless the embedding technique can become computationally efficient and stable, it should be bypassed in favor of the response matrix approach. (Author's abstract)

MODEL STUDY OF SALT-WATER INTRUSION TO A RIVER USING THE SHARP INTERFACE APPROXIMATION,
Kansas State Geological Survey, Lawrence.
C. D. McElwee.
Ground Water, Vol. 23, No. 4, p 465-475, July-August, 1985. 8 Fig, 1 Tab, 13 Ref.

Descriptors: *Saline water intrusion, *Rivers, *Water quality, *Smoky Hill River, *Kansas, *Model studies, *Saline-freshwater interface, Geochemistry, Geohydrology, Aquifers, Water pollution prevention.

Between Salina and Enterprise, Kansas, the salinity of the Smoky Hill River increases sharply. As a result, the river downstream at various times exceeds the recommended drinking-water-quality standards for chloride. The Smoky Hill and Kansas Rivers are important sources of water for several population centers in eastern Kansas; therefore, this problem has an impact on a significant part of the Kansas population. The source of the saline water is predominantly from groundwater dissolution of the Hutchinson Salt Member of the Wellington Formation of Permian age. The dissolution of the salt has caused a north-south trending collapsed zone called the Wellington aquifer to occur along the present eastern extent of the salt. A confining shale layer exists between the Smoky Hill alluvium and the Wellington aquifer in most areas. However, between New Cambria and Solomon, Kansas, the layer is thin and fractured, allowing the salt water to move up into the alluvium. The steady-state model presented in this study indicates that the saline water layer of the alluvium in the Smoky Hill River valley should be in an unstable condition near the river. This indicates that unstable interface upconing should be a dominant mechanism for supplying salt water to the river system. The time-varying model show
the response of the chloride discharge to a
event can be qualitatively explained by the
ble interface upconing mechanism. As the
stage rises, the saline water intrusion declin
the river stage declines, the saline water in
increases beyond its normal value and subs
the normal value over the period of a few
if no new flood events occur. During rising
stage, the river is supplying the ground
system, and the saline water intrusion or u
upconing is shut off. During falling river
bank storage and perhaps an elevated wate
cause the fresh groundwater discharge to be
er than normal, which in turn causes greate
normal saline water intrusion. In additio
time-varying model shows that several

Descriptors: *Soil water, *Neutron moisture meters, *Clays, Swelling soils, Soil texture, Density, Mathematical equations, Calibration, Measurement instrumentation, Irrigation effects, Water balance.

Neutron meters were calibrated for moisture determination in a layered swelling soil, showing changes in both swelling characteristics and texture with depth. The bulk density-moisture content relationship of each layer determined from small soil cores agreed with those predicted from in-situ swelling measurements taken during a previous study. The precision of calibration of two neutron meters were markedly improved by correcting for textural and bulk density changes with depth. The regressions of total moisture content on corrected neutron ratios were similar for the two moisture meters and comparable to those obtained for similar soils in previous studies provided that the same calibration techniques were used. For moisture determination in the field, separate calibration equations of volummetric moisture content against neutron ratios were required to account for the individual bulk density-moisture content relationship of each soil layer. The calibration equation for the surface layer had a markedly lower calibration coefficient and a much higher intercept constant than for the subsoil. Measured changes in soil moisture following irrigation using the above calibration equations of the neutron moisture meter agreed closely with values predicted by water balance within a large soil core in a lysimeter. Norwegian tills are usually coarse. The saturated water movement is mainly concentrated along fractures, fissures and sorted sediment zones. The studies indicate that less than 10% of the water drains through the pore system of the till matrix. There is no marked correlation between the grain-size composition of the till and the saturated permeability. Homogeneous Norwegian tills may form important conduits of capillary water transport from the groundwater level to the vegetation during dry summers. This is mainly because the tills are dominated by equidimensional minerals which form an open pore system and because the groundwater level in many cases is situated at shallow depths. Journal of Hydrology, Vol. 78, No. 1/2, p 107-121, May, 1985. 9 Fig, 1 Tab, 21 Ref. CSRS project CA-D*-LAW-4350-H.

Descriptors: *Infiltration, *Trickle irrigation, *Soil water, Irrigation, Unsaturated zone, Irrigation efficiency, Irrigation practice.

Galerkin's weighted residual method was used to numerically solve the two-dimensional nonlinear partial differential equation that describes the transient movement of water in an unsaturated porous medium. The model which had been successfully used to simulate the transient moisture movement in a homogeneous soil medium was applied in a newer version to one-dimensional vertical and two-dimensional steady-state moisture flow in a heterogeneous soil medium. The computed results in the vertical infiltration problem compared well with results obtained from a Hermitian finite-element model. The results of the steady-state pressure head distributions also compared well with experimental data from a trickle irrigation source. The advantages of the existing model to other simulation models are its ability to deal with moisture movements through a very dry soil environment in a homogeneous or heterogeneous medium, as well as its ability to treat the irregularly shaped flow regions which are usually difficult to model with other numerical models. ESTIMATING VERTICAL SOIL MOISTURE FLUX AT A LAND TREATMENT SITE,
California Univ., Santa Cruz. Dept. of Applied Science.
S. J. Dreiss, and L. D. Anderson.
Ground Water, Vol. 23, No. 4, p 503-511, July-August, 1985. 9 Fig, 1 Tab, 12 Ref, 1 Append.

Descriptors: *Soil water, *Land disposal, *Percolation, Path of pollutants, Soil saturation, Estimating, Soil matric suction.

In land treatment projects where wastes sludges or fertilizers are applied to the ground surface, these estimates are particularly important because subsurface water movement is the primary means of contamination migration. A sludge land treatment project that was the motivation for making percolation estimates is reviewed. The method used to compute percolation is presented and the results of the computations are discussed. Use of the zero flux plane hypothesis gives reasonable estimates of cumulative seasonal percolation when weekly measurements of moisture content and matric suction are used. A detailed description of the spatial variability of K-sat is not warranted with this method unless K-sat is very small. Soil-water percolation through marine terrace sediments in central California varies an order of magnitude between years of high and low rainfall. (Baker-IVI)

Descriptors: *Po River, *Italy, *Species composition, *Periphyton, Ecological distribution, Seasonal variation, Water temperature.

Seasonal factors, more than substrate exposure time, seem to control the dynamics of invertebrate colonization of air-dried Typha latifolia stems and leaves. Typha (about 500 g dry weight) was in baskets suspended in an artificial channel; the artificial channel was 22 m long, 60 cm wide, and fed by the waters of the Po River (Italy) at a constant flow rate of 1-2 cm/sec and water depth of 1 cm. Temperature, river discharge, photoperiod, dissolved oxygen, and substrate exposure time were correlated with the abundances of taxa found, after log (x+1) transformation. Water temperature, more than substrate exposure time, accounted for fluctuations in abundance. Some taxa responded to photoperiod more than water temperature. Only Bryozoa were dependent on substrate exposure time. Microhabitats provided by Typha allowed colonization by Glyptotendipes paripes. Most of the other taxa were periphyton dwellers and more or less euryecious; their colonization was mainly related to drift composition. The most abundant taxa were Naididae (Stylaria and Chaetogaster) and Chironomidae (Paratanytarsus mediterraneus, Cricotopus sylvestris, G. paripes); the gastropod Viviparus ater and the amphipod Echinogammarus stammeri were the most important in terms of biomass. DRIFT IN HAWAIIAN STREAMS,
Brigham Young Univ., Provo, UT. Dept. of Zoology.
J. R. Barnes, and D. K. Shiozawa.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2119-2124, 1985. 2 Fig, 1 Tab, 31 Ref.

Descriptors: *Aquatic drift, *Hawaii, *Streams, *Macroinvertebrates, Caddisflies, Turbellaria, Oligochaetes, Harpacticoida, Crustaceans, Animal behavior.

Macroinvertebrate drift patterns were studied in four Hawaiian streams. During sampling sunset was between 19:00 and 20:00 hr and sunrise between 06:00 and 07:00 hr; sampling lasted for 24 hr, and employed 30 x 10 cm drift nets with 110 micrometer mesh netting. Turbellaria, Oligochaeta, Chironomidae, Trichoptera, Decapoda, and Harpacticoida were collected in significant densities. Turbellarians were collected only in Waiahole stream, on the island on Oahu; they exhibited a typical bigeminous drift pattern, with the initial drift peak occurring just after sunset and a secondary peak a few hours before sunrise. Oligochaetes occurred in the drift of Paakea and Waiohue streams (on Maui island) and Hanakapiai (Kauai island), and Waiahole stream. No diel patterns were apparent on Maui, but a bigeminous peak was recorded for the Hanakapiai oligochaetes. The major peak occurred shortly after sunset and a secondary peak occurred just before sunrise. Chironomid drift from both Paakea and Waiohue streams showed no diel behavioral drift pattern. Midges in Hanakapiai drifted with an alterans pattern. Cheumatopsyche analis, and introduced trichopteran, had a unimodal peak just after sunset in Waiohue, Hanakapiai, and Waiahole and a bigeminous pattern in Paakea. A juvenile atyid shrimp, which was collected in both Paakea and Waiohue, had two color phases in the drift in Paakea. The light shrimp had a bigeminous pattern whereas the dark shrimp had a unimodal nocturnal drift pattern peaking several hours after midnight. The harpacticoid copepod Nitocra spinipes was collected in the drift of Paakea, Waiohue, and Hanakapiai. Those in Paakea followed the alterans pattern, those in Hanakapiai followed the bigeminous pattern, and the Waiosue population had an alterans pattern except for a daytime peak at 16:00, which could have been due to catastrophic drift. LIMNOLOGY OF A NATURALLY ACIDIC TROPICAL WATER SYSTEM IN AUSTRALIA; I. GENERAL DESCRIPTION AND WET SEASON CHARACTERISTICS,
AVCA, Sydney (Australia).
A. W. Morley, T. E. Brown, and D. V. Koontz.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2125-2130, 1985. 2 Fig, 2 Tab, 3 Ref.

Descriptors: *Jabiluka, *Magala River, *Australia, *Northern Territory, *Limnology, *Tropical regions, *Seasonal variation, Ecological effects, Mining, Billabongs, Fishkill, Mussels, Water pollution effects.

Major changes in water quality occur in the Magela Creek (Northern Territory of Australia) during the dry-to-wet season; as a consequence fish and other biota are significantly affected. The region in which the Magela Creek is located experiences a distinct wet and dry season, with 97% of the 1,530 mm annual rainfall occurring in the wet season (October-May). Average effective evaporation exceeds rainfall by approx 700 mm, a circumstance which is responsible for the formation of a series of discrete billabongs (water holes) of varying sizes throughout the area during the dry season. During the wet season the Magela floodplain is a continuous body of water 2-5 m deep. The waters of Magela Creek are naturally acidic and very soft, with low levels of nutrients. Regional climatic changes induce perturbations in water quality, as does ingress of groundwater into floodplain billabongs. Studies in 1979-80, 1980-81, 1981-82, and 1982-83 revealed fish kills of varying degrees of severity. In some cases acidic water with elevated aluminum levels was present at the time of the fish kills, but other kills had no obvious cause. Freshwater mussels (Velesunio angasi) also died in one of these events. The losses of biota were associated with the onset of flooding. After the floodplain became completely covered with water, water quality was excellent. Anthropogenic changes in water quality that may occur when Jabiluka uranium mining operations commence will be difficult to separate from the significant natural changes. (Rochester-IVI)

The degrees of change in water quality occurring in billabongs (water holes) of the Magela Creek floodplain (Australia) by the end of the dry season is primarily a function of the duration of the rain-free period, but depends additionally on other factors. Water chemistry changes correlate with fish-kills in some cases, but some fishkills have occurred without apparent cause. The dry season in this area is characterized by high temperatures and the absence of rainfall. By the end of the dry season surface water is lacking except for about 10 billabongs. Although the billabongs vary

cal parameters, phytoplankton, zoo- macrophytic vegetation of four eastern plains of Venezuela were tations. Overall, water temperatures 5.0-30.0 C, pH ranged from 4.9-7.1, en (DO) ranged from 1.4-9.2 mg/l, alues of color ranged from 14-40 Pt- rty-seven genera of phytoplankton e Uraco, 31 in the Yabo, 40 in the o, and 27 in the Claro; Chlorphyta phyta were the dominant groups. ragilaria, Surirella, Melosira, Tabel- icula were the most frequently re- . Maximum phytoplankton abun- ed with increased pH and DO s low phytoplankton numbers coin- cided with low values of these parameters. In order of predominance, rotifiers, copepods, cladocerans, and insect larvae were the dominant zooplankton groups. The rotifers were represented by 17 taxa in six eurotatorian families. No clear pattern of variations in rotifer dynamics was seen. Of the different rotifers, Keratella americana was most dominant, with a maximum density of 56 organisms/l noted in March in the Uracoa River. At the same station and in the same month, Brachionus, the second most dominant genus, was found at 36 organisms/l. Copepods had a maximum density (28 organisms/l) on the Yabo River in May, and cladocerans had their greatest abundance (18 organisms/l) in May and insect larvae had their greatest abundance (22 organisms/l) in September. Macrophyte cover was relatively high in the borders of the river channel during the rainy season. Overall, 19 macrophyte families were represented in the vegetation sampled at all the stations. RIVER TYPOLOGY OF SAO PAULO STATE, BRAZIL,
Instituto de Pesca, Santos (Brazil).
M. H. Maier, M. Takino, M. A. Basile-Martins, and M. N. Cipolli.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2161-2166, 1985. 1 Fig, 2 Tab, 5 Ref.

Descriptors: *River systems, *Sao Paulo State, *Brazil, *Physicochemical characteristics, Seasonal variation, Water temperature, Turbidity, Dissolved oxygen, Alkalinity, Conductivity, Silica, Iron, Chloride, Ammonia, Nitrites, Orthophosphate, Hydrogen ion concentration.

Characterization of seven rivers of Sao Paulo State, Brazil, was conducted based on physicochemical parameters sampled either on a short-term basis (June-September, Sapucai Guacu and Capivari), a long-term basis (a minimum of two complete seasonal cycles, Jaguari, Mogi Guacu, Piricicaba, and Jacare Pepira), or by both approaches (Ribeira de Iguape). Temperature, turbidity, dissolved oxygen, pH, alkalinity, conductivity, silica, iron, chloride, ammonia, nitrite, and orthophosphate were determined. The rivers could be divided (by cluster analysis) into two groups: AB, characterized by conductivity of 11-46 micro-Siemens/cm (micro-S) and alkalinity of 0.2-0.4 milliequivalents (m-eq)/liter, and CD, characterized by 55-82 micro-S/cm and 0.5-0.8 m-eq/l, respectively. Chloride values helped to identify the CD group (2.9-6.6 ppm), but for the AB group chloride results probably were distorted by the presence of sewage influx, particularly during July. Both the long-term investigation and the short-term one appeared adequate to characterize these lotic environments. (Rochester-IVI)

STRATIFICATION AND PRIMARY PRODUCTION IN A SMALL BRACKISH LAKE STUDIED BY CLOSE-INTERVAL SIPHON SAMPLING,
Abo Akademi, Turku (Finland). Dept. of Biology.
T. Lindholm, K. Weppling, and H. S. Jensen.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2190-2194, 1985. 6 Fig, 12 Ref.

Descriptors: *Stratification, *Primary production, *Brackish lakes, *Lake Holmsjon, *Aland, *Finland, Chemocline, Bacteria, Photosynthetic bacteria, Phosphorus, Ammonia, Nitrogen.

The importance of chemocline primary production was demonstrated in Lake Holmsjon, Aland (southwestern Finland), a basin incompletely isolated from the Baltic Sea and exhibiting temporary meromixis. A new in-situ incubator, with spirally-arranged arms at 5 cm depth intervals, was used for primary production measurements in the bacterial plate. Due to stratification, the water below 3.5-4 m was anoxic in both summers studied. The high clarity of water (Secchi depth: 2-4 m) permitted phototrophic bacteria to form dense populations in the lake. Complete overturn occurred in both autumms studied. The stagnant deep water had total phosphorus of 0.3-0.5 mg P/l and ammonia N 1-3 mg/l. Steep gradients of dissolved oxygen, pH, and Eh were found by siphon samplings. Special communities of phytoplankton and bacteria were revealed. A layer of Chlamydomonas sp occurred very close to, and even with, the anoxic zone, and was often associated with peaks of chlorophyll a and primary production. Conspicuous pigment and production peaks were encountered in the upper part of the anoxic zone where purple bacteria occurred. Maximum photosynthesis (184 mg C/cu m/hr) was observed in August in a thin, but very dense layer of Chromatium sp, with a bacteriochlorophyll a value of 484 microgram/l. In the strongly reducing, anoxic deep water, dense populations of green sulfur bacteria developed in both summers; bacteriochlorophyll d reached values up to 4,000 microgram/l, but photosynthetic activity was low, probably due to low light levels. A change to cloudy weather after a long sunny period was associated with a rise in the bacterial plate from 4.1 to 3.4 m depth in August 1982. Purple bacteria (Chromatium sp) were shown to migrate downward during the day and upward at night. (Rochester-IVI)

DIATOM FLORA OF THE LLOBREGAT RIVER AND ITS RELATION TO WATER QUALITY,
Barcelona Univ. (Spain). Dept. de Ecologia.
X. Tomas, and S. Sabater.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2348-2352, 1985. 4 Fig, 1 Tab, 5 Ref.

Descriptors: *Diatoms, *Llobregat River, *Spain, *Water quality, *Bioindicators, Species distribution, Species composition, Seasonal variation.

A diatom checklist of the Llobregat River (Spain) is reported, with comments on longitudinal distribution of species, environmental factors, and seasonal effects. Samples were collected at 18 stations along the 156-km length of the main stem, which runs from the Pyreness to the Meditteranean Sea. Except for the last two stations downstream, which are in an area receiving wastewater, diatoms were found everywhere in quantity throughout the year; 116 spp and 34 varieties were identified. The upper four stations covered a montane zone that includes the La Baells reservoir; species richness was moderate, with very few clearly dominant species: the combined relative abundances of Achnanthes minutissima, Cymbella minuta, Diatom hiemale var mesodon, and in winter, Meridion circulare, always exceeded 80%. The next several stations, covering the zone down to the confluence with the Anoia River, exhibited a gradual replacement of species of the first zone by species of Navicula and Gomphonema. Input of salts at the three stations above, at, and just below the confluence with the Gavarresa River enriched these communities; Nitzschia spp and Cyclotella spp, characteristic of the third zone, first appeared here. The last zone, which includes very polluted reaches affected by both industries and towns, extended from the confluence with the Anoia River to the Sea. Populations here were impoverished, with only some pollution-tolerant Nitzschia spp, especially N. frustulum and N. palea, some resistant Navicula spp (N. pelliculosa, N. atomus, and N. permitis), and centric diatoms in abundance. Principal components analysis of the log-transformed percentages of 44 spp suggested relationships between the floristic zones and environmental parameters and indicated seasonal aspects in the diatom flora. GRAYLING (THYMALLUS THYMALLUS (L.)) IN THE LOWER PART OF THE RAUTALAMPI WATERCOURSE, FINNISH LAKE DISTRICT,
Keski-Suomen Vesipiirin Vesitoimisto, Jyvaeskylae (Finland).
A. Eloranta.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2555-2559, March, 1985. 3 Fig, 2 Tab, 11 Ref.

Descriptors: *Fish populations, *Rautalampi, *Finland, *Graylings, *Lakes, Water temperature, Population dynamics, Spawning, Sport fisheries.

The history, biology and angling catches of grayling in the Rautalampi watercourse, Finland, are described. These fish are derived from the stocking, between 1922 and 1928, of some 182,000 newly-hatched embryos and fingerlings. The main study area was situated in the lower part of the Rautalampi watercourse and comprised 8 rapids and 5 large lakes. Spawning occurred from May 5th to 25th, when the water temperature exceeded 5.0 to 5.5 degrees C. All grayling reached sexual maturity by four years of age. Annuli were laid down on the scales at the start of the growth period in late April or early May. On the average there were 15-19 circuli on the scales of grayling after its first year of life. The oldest fish caught were in their seventh year of life. Males grew faster than females after the onset of sexual maturity. Somatic growth rate declined sharply after the middle of September. The rapids of the Rautalampi watercourse have been sport fishing areas since the beginning of the 1900s. Grayling catches from the lake areas were low, but those from the rapids were high, up to 26.6 kg/ha/a. The grayling is omnivorous and capable of changing flexibly from one food item to another, so that it does not get involved in disastrous food competition or starvation. (Baker-IVI)

CONTRIBUTION OF BACKWATERS TO THE ECOLOGY OF FISH POPULATIONS IN LARGE RIVERS. PRELIMINARY RESULTS ON FISH MIGRATIONS WITHIN A SIDE ARM AND FROM THE SIDE ARM TO THE MAIN CHANNEL OF THE RHONE,
Lyon-1 Univ., Villeurbanne (France). Dept. de Biologie Animale et Ecologie.
Y. Bouvet, E. Pattee, and F. Meggouh.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2576-2580, March, 1985. 7 Fig, 5 Ref.

Descriptors: *Fish migration, *Rhone River, *Backwaters, Rivers, Fish populations, Bullhead, Roach, Tench, Water temperature, Spawning, Seasonal variation.

Three species, the black bullhead, the roach, and the tench, have been seen to dominate the side arm and main channel of the Rhone river. Their occurrence turned out to be rather discontinuous in some stations over the year. Therefore the specimens were individually tagged. The bullhead spend the cold season in the upper reaches, burying into the sediment in winter. They are abundant until March and disappear in spring, probably migrating downstream, returning each year in autumn. Roach migrate up the arm in great numbers at 15 cm (two years of age) in the spring and spawn in the upper half of the arm. After about a month they disappear again, leaving these stations to the fry. Unlike that of the bullhead, the main migration of the roach does not seem to be governed by temperature. Most species of tench in the arm are large, about 40 cm, and old, about 8 to 12 yr. Therefore, their biomass is much more important than their numbers. Some tench are found in summer at the last station upstream, the only fish there at that time. Some quite sedentary specimens were recaptured on the same spot after about 100 days. Others had travelled only small distances and have not migrated downstream in the spring and upstream in autumn. (Baker-IVI)

LIMNOLOGY AND FISHERIES MANAGEMENT IN ZIMBABWE,
Lake Kariba Fisheries Research Inst., Kariba (Zimbabwe).
B. E. Marshall.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2671-2675, March, 1985. 1 Fig, 5 Tab, 16 Ref.

Descriptors: *Zimbabwe, *Limnology, *Fisheries management, Lakes, Reservoirs, Morphoedaphic Index, Fisheries, Fish populations, Model studies, Primary productivity, Conductivity, Phosphorus.

There are no natural lakes and few perennial rivers in Zimbabwe. About 100 large impoundments covering 43,500 ha and Lake Kariba with an area of 536,400 ha are the principal sources of fish at present. Morphometry and conductivity data are available from 33 of them, phosphates from 30, and primary production statistics only from four. While the use of empirical models is often obligatory in a developing country, there is concern about their accuracy, and because of the almost complete lack of fishery data it is difficult to verify them. The Morphoedaphic Index (MEI) is a simple and widely-used empirical model. Since the parameters are easy to estimate the MEI is particularly valuable in areas where detailed limnological studies are lacking. Conductivity is largely controlled by the major dissolved cations (calcium, magnesium, sodium and potassium), but the conductivity of Lake McIlwaine is less closely related and probably influenced by other dissolved material. This supports earlier views that using MEI in culturally enriched lakes is of doubtful validity, thus causing three Zimbabwean lakes (McIlwaine, Upper and Lower Umguza) to be excluded from further study. Recent works suggest that African reservoirs are more productive than natural lakes. Phosphorus is the major limiting nutrient in Zimbabwean lakes, except for some montane ones and those which have been culturally enriched. Most Zimbabwean data are orthophosphate, but this can be changed to total phosphorus for the MEI model. Fish yields were lower than those predicted by the MEI but higher than those from primary production. Too little is presently known about phosphorus in most Zimbabwean lakes, but the model may be useful for future estimations. (Baker-IVI)

FISHING AND HYDROLOGIE IN THE CENTRAL AMAZON (PECHE ET HYDROLOGIE EN AMAZONIE CENTRALE),
Universidade Federal do Rio de Janeiro (Brazil). Dept. de Biologia Marinha.
S. R. P. Annibal.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, Part 4, p 2692-2697, March, 1985. 4 Fig, 12 Ref.

Descriptors: *Fisheries, *Hydrology, *Amazon Basin, *Brazil, *Lago do Rei, Lakes, Commercial fisheries, Flooding, Fish, Population dynamics, Seasonal variation, Limnology, Varzea lakes.

Hydrologic characteristics directly affect fisheries; hydrology also affects the dynamics of exploited flooded regions in the Amazon Basin of Brazil. A study was conducted on a large varzea lake in the central Amazon and two sympatric species of commercial fish. The lake, Lago do Rei, is located on an island in the Amazon River. Data were collected on the hydrology, limnology, biology, and fish of the lake. There is a great variability in the profitability of fishing in the inundation zones of the Amazon. Considering the diversity of the existing fish fauna and the complex ecological interrelations in this region, fish culture should be based on population dynamics, environmental factors and human factors, so that an appropriate seasonal strategy can be proposed for each region. ASSESSMENT OF ECOLOGICAL CHANGES DURING THE RECENT HISTORY OF LAKE ONTARIO BASED ON SILICEOUS ALGAL MICROFOSSILS PRESERVED IN THE SEDIMENTS,
Michigan Univ., Ann Arbor. Great Lakes Research Div.
E. F. Stoerner, J. A. Wolin, C. L. Schelske, and D. J. Conley.
Journal of Phycology, Vol. 21, No. 2, p 257-276, June, 1985. 11 Fig, 2 Tab, 80 Ref. EPA grant R810396 and NSF grant OCE-8216588.

Descriptors: *Lake Ontario, *Algae, *Paleolimnology, *History, *Ecology, Diatoms, Chrysophyta, Limiting nutrients, Eutrophication, Phosphorus, Silica, Succession, Species composition.

Quantitative analysis of siliceous algal microfossils (diatoms and chrysophytes) in a radiometrically dated core of Lake Ontario sediments shows striking modifications of the flora produced and preserved, apparently as a result of anthropogenic modification of nutrient loadings to the lake. Qualitatively similar microfossil assemblages were deposited during the period ca. 1700-1815. A single major event is recorded in assemblages deposited ca. 1769. Between this event horizon and ca. 1815 there was an apparent increase in algal production, but minimal change in species composition. A major disturbance occurred at the level of the Ambrosia horizon, ca. 1831-1847. Assemblages deposited between ca. 1855 and 1900 indicate increasing eutrophication. It is inferred that silica limitation became important by about 1860 and that the system reached its greatest effective production ca. 1900. Major modification of the flora occurred in the period ca. 1900-1945, with most local extinctions of major indigenous populations occurring ca. 1920-1945. Assemblages deposited in the period ca. 1945-1975 are composed of some stenothermal populations also present in pre-disturbance assemblages, a large component of benthic and nearshore planktonic species, and a number of apparently planktonic populations rarely recorded from large temperate lakes, particularly species of the genus Nitzschia. The results indicate that the major factor driving species succession in Lake Ontario was phosphorus enrichment and consequent depletion of available silica supplies. The results also show the importance of a species' physical niche in determining its survival under these conditions. (Author's abstract)

PALAEOLIMNOLOGICAL RECORD OF HUMAN DISTURBANCE FROM HARVEY'S LAKE, VERMONT: GEOCHEMISTRY, PIGMENTS AND DIATOMS,
Minnesota Univ., Minneapolis. Limnological Research Center.
D. R. Engstrom, E. B. Swain, and J. C. Kingston.
Freshwater Biology, Vol. 15, No. 3, p 261-288, June, 1985. 11 Fig, 1 Tab, 78 Ref.

Descriptors: *Harvey's Lake, *Vermont, *Geochemistry, *Diatoms, *Lake sediments, Stratigraphy, Sediments, Environmental effects, Land use, Phytoplankton, Primary production, Cyanophytes.

Stratigraphic analyses of inorganic geochemistry, pigments and fossil diatoms in a 0.7 m core of profundal sediments were used to reconstruct the limnological history of Harvey's Lake, Vermont, over the last 1000 years. The lake is moderately productive, deep (44m) and clear, and the phytoplankton today is dominated by the blue-green alga, Oscillatoria rubescens. Sedimentary pigments unique to blue-green algae, oscillaxanthin and myxoxanthophyll, provide a detailed history of changes in the O. rubescens population. Accurate sediment chronology is derived from Pb-210, Cs-137 and C-14 dating and from the stratigraphy of pollen and sawmill wastes. Primary production increased in Harvey's Lake in 1780 following European settlement and again after 1945, as shown by greater accumulation of sedimentary pigments and diatom frustules, and changes in fossil algal assemblages. Blue-green algae first appeared in abundance about 1945, indicating nutrient enrichment from dairy wastes and shoreline development. Increased deposition of elements associated with clastic minerals also suggests greater soil erosion during both of these intervals. Two episodes of increased sedimentary anoxia (1820-1920 and 1945-present) are marked in the sedimentary record by enhanced pigment preservation, changes in authigenic Fe and Mn stratigraphy, and the development of laminated sediments. The earlier episode of oxygen depletion is correlated with the discharge of sawmill wastes into the lake, and the later episode is associated with increased primary production. Based on these data a new model for Fe and Mn sediment stratigraphy was developed for lakes that do not undergo complete hypolimnetic anoxia. Fine-scale resolution of recent diatom and oscillaxanthin stratigraphy provides historical evidence for a long-term negative interaction between diatom and blue-green algal populations in Harvey's Lake. Descriptors: *Macroinvertebrates, *LaTrobe River, *Victoria, *Australia, *Species composition, Species distribution, Ecology, Animal behavior, Food habits, Physicochemical characteristics.

Seventeen sites were each sampled six times over 2 years for macroinvertebrates. A range of physicochemical variables was also measured to determine which factors were related to the distribution of species. Numerical classification of the faunal data indicated that four groups of sites or communities were distinguishable: lowland sites; sandy upland sites; cobble upland sites from the northern catchment; and cobble upland sites from the southern catchment. Multiple discriminant analysis and multiple regression analysis demonstrated that particle size of the sediment, concentration of dissolved ions and altitude were the physicochemical features that were most strongly associated with changes in the faunal distribution. Abundances of shredders and predators did not vary between the site groups while those of scrapers, gatherers and filterers did: scrapers were most abundant at cobble sites while gatherers and filterers were least abundant on sand and increased in abundance downstream. The distribution of the feeding groups showed some similarity with that predicted by the River Continuum Concept, but the fact that the shredders did not decrease in abundance downstream was a notable difference. Abundance of total fauna at a site was inversely related to the amount of benthic organic matter. This feature is contrary to the pattern usually reported from rivers in the northern hemisphere.

Loop analysis is a qualitative network technique which is useful for delineating pelagic foodwebs and for predicting production relationships. Loop models were fitted to data sets for three lakes in Kejimkujik National Park, Nova Scotia. Using qualitative correlation signs, there was 80-89 percent agreement of model predictions an data values. Individual networks were integrated by summarizing linkages between pairs of variables. The resultant core network is a three-layered structure with 5 nutrient, 4 algae, 1 detritus and 10 zooplankton variables. The phytoplankton components utilize different types of nutrient complexes in each lake. Bluegreen algae have a special relationship to ammonia in Beaverskin Lake. Crustacean zooplankton consume phytoplankton directly whereas rotifers are connected to the foodweb via the detrital pool. In contrast to the multivariate statistical results reported previously, loop analysis furnished some robust evidence of the inherent structure in these plankton communities. Qualitative methodology also helps identify casual pathways in the ecological networks. The analysis illustrated which links are oscillating the most and which are expected to remain resilient with increasing perturbation. The models suggest several aspects of these communities that could be verified experimentally. (Author's abstract)

Descriptors: *Productivity, *Benthos, *Livingston Reservoir, *Texas, *Reservoirs, Primary productivity, Secondary productivity, Phytoplankton, Species diversity, Midges, Oligochaetes.

Physical-chemical conditions, phytoplankton productivity, community structure and productivity of the macroinvertebrate benthic community were determined during 1976-77 in the subtropical Livingston Reservoir (Texas). Physical-chemical results revealed high nitrate and phosphate concentrations with highest values in the riverine segment. Large phytoplankton populations were present during most of the year. Phytoplankton productivity was high, producing an annual mean of 87 mg C/cu m/h (12 hours light/day). High turbidity in the riverine segment limited phytoplankton productivity during winter and spring. Macrobenthos was dominated by chironomids (Chironomus, Procladius, Coelotanypus and Tanypus) and oligochaetes (Limnodrilus). The annual mean benthic population was estimated at 1,626/sq m with a mean dry weight of 0.66 g/sq m. Mean benthic species diversity was 1.80. A lacustrine-riverine community gradient was revealed. Benthic productivity was 6.8 g/sq m/yr (dry weight) with a P:B ratio of 10. A low correlation was observed between benthic and phytoplankton productivity, and between phytoplankton standing crop and benthic macroinvertebrate numbers throughout the reservoir. Algal food supplies had little impact on the benthic community which was composed predominately of species which fed mostly on organic detritus. Stressful conditions caused by low dissolved oxygen concentrations probably inhibited development of the benthic community throughout the reservoir during summer months, while high sedimentation rates limited development in the head waters. PHOTOSYNTHETIC ACTIVITY OF DOMINANT ALGAL SPECIES IN EUTROPHIC SHALLOW LAKE (GROSSER MUGGELSEE, BERLIN) INVESTIGATED BY MICROAUTORADIOGRAPHY,
Akademie der Wissenschaften der DDR, Berlin. Inst. fuer Geographie und Geooekologie.
B. Nixdorf.
Internationale Revue der Gesamten Hydrobiologie, Vol. 70, No. 2, p 237-246, 1985. 8 Fig, 16 Ref.

Descriptors: *Muggelsee, *Berlin, *Germany (Democratic Republic), *Photosynthesis, *Autoradiography, *Eutrophic lakes, Phytoplankton, Productivity, Biomass, Cyanophyta, Diatoms, Isotope studies.

The photosynthetic activity of dominant phytoplankton in a eutrophic shallow lake was investigated by the autoradiographic method in 1979 and 1980. It was shown by light and dark field microscopy that all species of Cyanophyta (Oscillatoria redekei, Oscillatoria agardhii, Aphanizomenon flos-aquae) were characterized by a continuously high uptake of C-14 labeled NaHCO3. Similarly high photosynthetic activity was observed during the occurrence of Cryptomonas sp. and nanoplankton. Contrary to these observations, diatoms showed remarkably high portions of photosynthetically inactive biomass when their development was abundant. The reasons for this discrepancy between high biomass of diatoms and relatively low primary production (measured by the C-14-method and autoradiography) are discussed. (Author's abstract)

COMPOSITIONAL AND STRUCTURAL ANALYSIS OF PHYTOPLANKTON IN LAKE KHURPATAL, (U.P.), INDIA,
Kumaun Univ., Naini Tal (India). Dept. of Zoology.
M. C. Pant, S. Jaiswal, and A. P. Sharma.
Internationale Revue der Gesamten Hydrobiologie, Vol. 70, No. 2, p 269-280, 1985. 6 Fig, 4 Tab, 36 Ref.

Descriptors: *Phytoplankton, *Lake Khurpatal, *India, *Physicochemical properties, Dinoflagellates, Biomass, Species composition, Species diversity.

The phytoplankton community in Lake Khurpatal (Kumaun himalya), India, was analyzed in relation to physico-chemical variables. Phytoplankton biomass ranged from 2.7 to 20.0 g/cu m in the euphotic zone of the lake. Dinoflagellates monopolized the algal community with a mean annual contribution of 94.5% to the total phytoplankton biomass. The community coefficient used to quantify the seasonal changes in algal population reflected the fact that successional episodes were not very significant, the percentage similarity among the consecutive algal samples ranging from 47.8 to 89.9%. The phytoplankton community was characterized by low species richness, low equitability and species diversity. Various ecological characteristics of the community are discussed and the phytoplankton biomass is also compared with that of some tropical and temperate lakes. (Author's abstract)

The zooplankton community of eutrophic Lahontan Reservoir, Nevada was studied during a 22-month period of 1980 and 1981. The zooplankton community consisted of seven species of cladocerans, two species of copepods and nine species of rotifers. The dominant zooplankters were the cladocerans Daphnia galeata, D. schodleri, Diaphanosoma leuchtenbergianum, and Bosmina coregoni, the copepods Cyclops vernalis, and Diaptomus sicilis, and the rotifer Keratella. Mean zooplankton density was 37.2/l in 1980 and 64.7/l in 1981. Overall, copepods comprised 50 percent, cladocerans 34 percent, and rotifers 16 percent of the total population. Biotic and abiotic factors are discussed in relation to their potential influence on zooplankton community structure. (Author's abstract)

RECOVERY OF A STREAM INVERTEBRATE COMMUNITY FROM A FLASH FLOOD IN TESUQUE CREEK, NEW MEXICO,
New Mexico Univ., Albuquerque. Dept. of Biology.
M. C. Molles, Jr.
Southwestern Naturalist, Vol. 30, No. 2, p 279-287, May, 1985. 2 Fig, 2 Tab, 27 Ref.

Descriptors: *Benthos, *Streams, *Tesuque Creek, *Santa Fe National Forest, *New Mexico, *Flash floods, *Floods, Ecological effects, Biomass, Species diversity, Streambeds, Flood damage.

In mid-August 1977, a flash flood disrupted the benthic community of one fork of Tesuque Creek, Santa Fe National Forest, New Mexico. One year after the disturbance, the invertebrate communities of flooded and unflooded forks were similar in biomass, numbers, and species diversity. However, even after 2 years some difference in community composition remained. Oligochaetes showed no clear effect from the flood or its aftermath. Diptera recovered rapidly. Ephemeroptera, Plecoptera and Trichoptera recovered at intermediate rates, and Coleoptera recovered most slowly. Recovery proceeded at approximately equal rates upstream and downstream from the undisturbed fork. Comparing preflood to postflood collections yielded approximately the same picture of recovery as comparing postflood collections from undisturbed and disturbed reaches. (Author's abstract)

COLLOIDAL STABILITY OF PARTICLES IN LAKES: MEASUREMENT AND SIGNIFICANCE,
Johns Hopkins Univ., Baltimore, MD. Dept. of Geography and Environmental Engineering.
W. Ali, C. R. O'Melia, and J. K. Edzwald.
Water Science and Technology, Vol. 17, No. 4/5, p 701-712, 1985. 5 Fig, 2 Tab, 18 Ref. NSF grant CEE81-21501.

Descriptors: *Particulate matter, *Particle stability, *Colloids, *Lakes, Aggregation, Fate of pollutants, Colloids, Model studies, Simulation, Hydraulic loading, Dissolved solids, Organic carbon, Solid-solute partitioning.

Under certain chemical conditions, contacts between particles in lakes result in attachment of the colliding particles to form aggregates (the process of coagulation). Model simulations of the effects of particle stability, solid-solute partitioning, and hydraulic loading on the transport and fate of particles and associated pollutants and nutrients were made. Lakes vary widely in hydraulic loading and pollutants vary widely in partition coefficients. Natural particles are rather unstable in lakes, but colloid stability is expected to depend on the hardness and dissolved organic carbon in the water; these also vary widely among lakes. As a result, lacustrine systems are expected to differ appreciably in their ability to assimilate pollutants. A model has been developed to provide a basis for predicting deposition and pollutant concentration in these systems. (Moore-IVI)

PHOSPHORUS, NITROGEN AND CHLOROPHYLL-A CONCENTRATIONS IN A TYPICAL DUTCH POLDER LAKE, TJEUKEMEER, IN RELATION TO ITS WATER REGIME BETWEEN 1968 AND 1982,
Limnologisch Inst., Oosterzee (Netherlands). Tjeukemeer Lab.
H. De Haan, and J. R. Moed.
Water Science and Technology, Vol. 17, No. 4/5, p 733-743, 1985. 7 Fig, 2 Tab, 14 Ref.

Descriptors: *Phosphorus, *Nitrogen, *Chlorophyll a, *Tjeukemeer, *Netherlands, Polder lakes, Hydrologic budget, Climate, Limiting nutrients, Chlorophyll a, Algae, Eutrophication.

Tjeukemeer is the largest lake in the province of Friesland, The Netherlands. The lake is connected with other lakes in the region by canals; the interconnected lake system is used to regulate the water table of the low-lying surrounding polders. The mean concentrations of total phosphorus and total nitrogen in the Tjeukemeer during the summer season between 1968 and 1982 were 0.215 and 3.8 mg/l, respectively. These values exceeded water quality standards for The Netherlands. Though the mean summer chlorophyll-a (chl-a) concentration of 116 micro-g/l for 1968-1982 was comparable with that for the basic quality standard, the mean concentrations between 1977 and 1982 were from 1.3 to 2.1 as high. Multiple regression analysis demonstrated that the P and N concentrations in Tjeukemeer in summer and in winter were significantly correlated with the deficit or surplus of water and consequently with the man-made regime. Between 1979 and 1982 the ratios (w/w) of the mean concentrations of total N and total P and those of particulate N and particulate P in summer were less than 16 and 10, respectively, indicating that phytoplankton growth was N rather than P limited. QUANTIFICATION OF WIND INDUCED RESUSPENSION IN A SHALLOW LAKE,
Agricultural Univ., Wageningen (Netherlands). Dept. of Water Pollution Control.
R. H. Aalderink, L. Lijklema, J. Breukelman, W. van Raaphorst, and A. G. Brinkman.
Water Science and Technology, Vol. 17, No. 6/7, p 903-914, 1985. 5 Fig, 2 Tab, 10 Ref, 2 Append.

Descriptors: *Resuspension, *Wind, *Lakes, *Suspended sediments, Mass balance, Sedimentation, Wave action, Shear stress, Mathematical models.

The mass balance of suspended solids in a shallow lake was modelled as the net result of resuspension and settling. Four different formulations for the flux of resuspension were used. Two equations were based on the conception of wave induced resuspension, the other two used the flow field induced shear stress as the driving force for resuspension. Parameter estimations based on experimental time series of wind velocity and SS concentration produced lower least square values with the models based on flow induced resuspension. The model parameter representing settling was in reasonable accordance with the settling velocity obtained from sediment traps. The spread in results can be explained by a lack of homogeneity and horizontal transport. (Author's abstract)

Descriptors: *Chemical composition, *Lake Zemborzyce, *Poland, *Bottom sediments, Chemical analysis, Sedimentation, Lakes, Lake sediments.

An analysis was made of the chemical composition of bottom sediments in the man made Lake Zemborzyce near Lublin. Chemical composition of the sediments and its possible relation to the specific composition and percentage content of the systematic groups in the total numbers of phytoplankton was also studied. The content of carbon, nitrogen, and calcium in the reservoir bottom is shown on maps. No relationship appeared to exist between the composition of phytoplankton and the content of the basic available biogens in the sediments. (Baker-IVI)

Nature, Vol. 315, No. 6019, p 455-456, June, 1985. 1 Fig, 6 Ref.

Descriptors: *Drought, *Plant physiology, *Water stress, Water requirements, Water potentials, Crassulacean acid metabolism.

Plants subjected to periodic or constant water stress display crassulacean acid metabolism (CAM), which is a photosynthetic strategy. A similar phenomenon was recently, surprising, observed in an oceanic member of the Crassulaceae, Umbilicus rupestris (wall pennywort) in response to a drought situation. Some succulent species of plants accumulate acid in their tissues during the night. Leaf acidification is accompanied by the nocturnal uptake of carbon dioxide and a temporary fixation of carbon by the enzyme phosphoenolpyruvate carboxylase into a 4-carbon compound, oxaloacetate. This was subsequently converted to malate. There are clear energetic advantages in the adoption of a flexible system in which it is possible to switch to CAM only during periods when it is of advantage to the survival of the plant, such as in times of water stress. Some species switch to an incomplete form of CAM when experiencing drought. This type of CAM idling has been noted in Umbilicus rupestris when exposed to drought conditions. Evidently the falling water potentials in the plant activate a metabolic switch, but the nature of the operation of this switch is still unknown. Why an oceanic species should posses this unusual capacity for dealing with drought appears to be related to its preferred habitat. Umbilicus rupestris grows in cliff crevices and stone walls, and sometime even grows as an epiphyte in larger plants. In such exposed locations the threat of drought is very real. (Baker-IVI)

2J. Erosion and Sedimentation

EFFECT OF KINETIC ENERGY OF EXCESS RAINFALL ON SOIL LOSS FROM NON-VEGETATED PLOTS,
Commonwealth Scientific and Industrial Research Organization, Canberra (Australia). Div. of Soils.
P. I. A. Kinnell.
Australian Journal of Soil Research, Vol. 21, No. 4, p 445-453, 1983. 5 Fig, 1 Tab, 13 Ref.

Descriptors: *Kinetic energy, *Rain, *Soil loss, Sheet erosion, Soil erosion, Rainfall intensity, Infiltration, Acceptance rate.

In situations where much of the energy required to generate erosion is derived from raindrop impact, soil loss is greatest when runoff occurs. The energy of raindrops is therefore less effectively used in generating soil loss when runoff is absent than when runoff is present. Data obtained from three 0.01 ha runoff and soil-loss plots, established with a bare fallow treatment on a yellow podzolic (Albaqualf) soil and slope gradient of 4.2%, were analyzed in terms of the kinetic energy of raindrops and the efficiency of the use of that energy in generating soil loss. The difference between rainfall intensity and the average infiltration (acceptance) rate of the soil during an event can be used to estimate variations in the efficiency of use of rainfall energy in generating sheet erosion. The product of the rainfall kinetic energy and the excesses in rainfall intensity may prove to be a useful index of the ability of rain to cause sheet erosion, but the product should not be considered as a direct substitute for EI30 in the Universal Soil Loss Equation. ESTIMATION OF DISCHARGE AND LOADS FROM THE RIVERS FLOWING INTO LITTORAL SEAS OF CHINA (IN CHINESE),
Academia Sinica, Beijing (China). Inst. of Geography.
T. Cheng, and C. Zhao.
Acta Geographica Sinica, Vol. 39, No. 4, p 418-427, December, 1984. 2 Fig, 6 Tab, 9 Ref.

Descriptors: *China (Peoples Republic), *River flow, *Sediment loads, *River, *Seas, *Coastal waters, *Donghai, *Nanhai, *Pacific Ocean, *Bohai, Rivers, Sediment transport, Seasonal variation, Annual distribution, Precipitation.

Based on the data collected from 164 hydrological stations situated at downstream river regions (3022 station years up to 1979) the annual averages of runoff and loads flowing into the seas from the rivers in littoral areas of China were estimated; they are approximately 1800 cu km and 2000 million tons respectively and account for 4.6% and 11.5% of the total world volume, while the content of soluble substances in the runoff is about the same as that of the world. Under annual average, the Donghai receives most of the discharge (approximately 64.5% of the total), Nanhai comes next, and the Pacific receives the least. The distribution of runoff that empties into the seas both in dry and wet years is comparable to that of the annual average; the most apparent variation of dry and wet years is observed in Bohai, while variation in Donghai and the Pacific are not as apparent. The Bohai also show the most apparent variation in sediment transport. During 1970-1979, both runoff and loads discharged into Bohai decreased and increased in Nanhai. In addition to the impact of periodic variation of precipitation in drainage areas, the increase and decrease of runoff is also affected by human activities; an example is when the precipitation of drainage areas varies little but, due to human activities, the runoff decreases. Since the last decade, the amount of runoff discharged into Donghai decreased slightly, but the loads increased accordingly; an increase of 5.4% has been observed. Yearly and seasonal variations of runoff and loads discharged into the seas are controlled by the major rivers that emptied into the sea areas. The variation of runoff and loads of most rivers within the sea area are consistent with each other. (Author's abstract)

Water Science and Technology, Vol. 17, No. 6/7, p 891-901, 1985. 14 Fig, 6 Ref.

Descriptors: *Sediment erosion, *Cohesive sediments, Chikugo Estuary, Japan, Shear stress, Estuaries, Velocity, Simulation, Mathematical models.

Tests on erosion of the cohesive sediments in the Chikugo estuary in Japan were conducted. The results indicate that the decrease in the rate of erosion at constant shear stresses is caused rapidly 20 to 30 minutes after the start of tests and that the decrease in caused by the increase in the solid fraction and the yield value of the sediment remaining uneroded due to shear stress. In order to simulate the erosion process of sediments, a model in which the increase in the yield value of sediment is assumed to be proportional to the integration value of the absolute value of the sediment velocity gradient with respect to time was developed. The simulation based on this model is shown to be available to estimate the amount of sediments eroded in the erosional process of cohesive sediments. (Author's abstract)

CALCULATION OF TRANSPORT COEFFICIENTS OF PHOSPHATE AND CALCIUM FLUXES ACROSS THE SEDIMENT-WATER INTERFACE, FROM EXPERIMENTS WITH UNDISTURBED SEDIMENT CORES,
Technische Hogeschool Twente, Enschede (Netherlands). Dept. of Chemical Technology.
W. van Raaphorst, and A. G. Brinkman.
Water Science and Technology, Vol. 17, No. 6/7, p 941-951, 1985. 4 Fig, 4 Tab, 15 Ref.

Descriptors: *Sediment-water interfaces, *Phosphates, *Calcium, *Solute transport, Lake sediments, Interstitial water, Benthic environment, Desorption, Chemical kinetics.

Transport of dissolved materials across the sediment-water interface is an important factor, affecting the chemical characteristics of lakes. For calculating benthic fluxes, concentration gradients and transport coefficients have to be known. Fluxes of phosphate and calcium across the sediment-water interface of six undisturbed cores from a shallow lake were investigated in the laboratory. Study of the accuracy of porewater extraction and the influence of this sampling upon the experiments indicates that sampling time should at least be one day. Continuous and batch experiments resulted in a rapid release of phosphorus and calcium from the sediment. The influence of induced seepage could not be shown. On a theoretical base, the benthic fluxes are fed by desorption at or just below the interface, rather than by diffusion from deeper layers. Interstitial water data could not directly be used for calculating the driving forces of these fluxes. Instead, end-concentrations in the overlaying water of the batch experiments are used, which resulted in transport coefficients which are in good agreement with theoretical as well as field data. A good interpretation of measured fluxes is only possible when a good estimation can be made of the kinetics of the chemical reactions in the sediment; core experiments should be accompanied by such analysis. Values for the equilibrium concentration are needed, which can best be obtained from batch experiments. Core experiments can be useful in studying the transport of solutes across the sediment-water interface. (Moore-IVI)

DISSOLVED INORGANIC PHOSPHORUS IN STREAMS OF THE INDIAN ARID ZONE,
Central Arid Zone Research Inst., Jodhpur (India).
J. S. Choudhari.
Journal of Hydrology, Vol. 78, No. 1/2, p 49-59, May, 1985. 6 Fig, 3 Tab, 19 Ref.

Descriptors: *Inorganic phosphorus, *Phosphorus, *Nutrients, *Luni River basin, *India, *Streams, *Deserts, Arid climates, Intermittent streams, Suspended solids, Lithology, Slopes.

Streams of arid regions, which flow only in direct response to torrential rainfall have not been studied for P concentration. Total dissolved inorganic phosphorus concentrations in stream waters of the Luni River basin in the northwest-Indian desert were determined during 1980 and 1981; previous reports indicate that dissolved inorganic P constitutes a major portion of total P in those stream waters. The P concentration varied between 0.03 to 4.56 micro-g/ml PO4(-3) in various streams. The Upper Luni, Mitri, Khari and Sagi streams showed higher concentrations of P during both years of study compared to those of the Guhiya, Bandi, Jojri and Khari Bandi streams. This could possibly

be due to variation in soil cover and slope gradient. Former streams draining hilly terrain with shallow gravelly weathering surfaces and greater slopes, could have increased the effective soil mass that interacted with runoff and generated higher concentrations of P. Suspended solids, produced by low-energy runoff from dry, loose soil surfaces formed during dry periods, and flow characteristics govern the concentration of total dissolved P in streams of the Indian arid region. Flow characteristics, lithology, transmission losses and soils which control the production and transportation of suspended solids influence the P concentration of stream waters in this arid region. EFFECTS OF WATERLOGGING AND SUBSEQUENT DRAINAGE OF A PASTURE SOIL ON PHOSPHATE SORPTION, EXTRACTABLE PHOSPHATE AND OXALATE-EXTRACTABLE IRON,
New South Wales Dept. of Agriculture, Rydalmere (Australia). Biological and Chemical Research Inst.
J. Bradley, I. Vimpany, and P. J. Nicholls.
Australian Journal of Soil Research, Vol. 22, No. 4, p 455-461, 1984. 3 Fig, 26 Ref.

Descriptors: *Waterlogged soils, *Drainage effects, *Phosphates, *Iron, Pastures, Sorption, Soil chemistry, Seasonal variation, New South Wales.

Undisturbed cores of a pasture soil from the central tablelands of New South Wales were waterlogged for periods varying from 4 to 42 days and then drained to simulate seasonal waterlogging. Phosphate sorption, Bray 1 extractable phosphate and oxalate-extractable iron levels were measured before watering, at the end of waterlogging and up to 90 days after draining. Increasing the duration of waterlogging increased the logarithms of phosphate sorption and Bray 1 extractable phosphate linearly, but the response equation of log oxalate iron was significantly quadratic. When drained, all three levels fell, but the positive sorption response to waterlogging remained 90 days after draining. These results are consistent with those from previous studies that found phosphate solubility to be associated with the reduction of iron during waterlogging and its subsequent oxidation on drying. The agronomic implication of the findings for superphosphate topdressing of seasonally waterlogged soils is discussed. (Author's abstract)

DOMINANT SHEAR STRESSES IN ARRESTED SALINE WEDGES,
Thessaloniki Univ., Salonika (Greece). Dept. of Civil Engineering.
V. Dermissis, and E. Partheniades.
Journal of Waterway, Port, Coastal and Ocean Engineering, Vol. 111, No. 4, p 733-752, July, 1985. 10 Fig, 17 Ref. NSF grant ENG. 76-11537-A01.

Descriptors: *Saline wedge, *Shear stress, Mathematical models, Velocity, Saline-freshwater interfaces, Friction, Bed resistance, Density.

The shear stresses in saline wedges have been investigated in a 20 m long variable slope flume by the following approaches: (1) Direct measurements of velocities and Reynolds stresses through hot film anemometers; (2) integration of the equations of motion; (3) Schijf-Schoenfeld's one-dimensional model; (4) integration of the equations of motion assuming zero bed stress. It was found that the interfacial and bed friction coefficients, fi and fo, respectively, can best be correlated with the number ReFr sq, in which Re is the Reynolds number, and Fr is the nondensimetric Froude number and with the relative density delta p/p taken as an independent parameter. The results are given as a family of curves with each curve corresponding to a specific delta p/p. The scattering of data is small and the agreement with results of earlier studies is good. Values of fi determined by the first two approaches agree closely, as do values obtained by the third and fourth approach. However the latter are substantially higher than the first. This is indicative of a strong effect of the bed resistance on the interfacial friction. (Author's abstract)

PREDICTED EXTREME HIGH TIDES FOR CALIFORNIA: 1983-2000,
Scripps Institution of Oceanography, La Jolla, CA.
B. D. Zetler, and R. E. Flick.
Journal of Waterway, Port, Coastal and Ocean Engineering, Vol. 111, No. 4, p 758-765, July, 1985. 1 Fig, 4 Tab, 6 Ref. Office of Naval Research contract N00014-83-C-0182.

Descriptors: *California, *Tides, *Prediction, Forecasting, Coastal areas, Design criteria, Spring tides, Perigean tides, Tropic tides, Perihelion tides.

The combination of high tides and storm-induced waves were devastating to the coast of California during the winter of 1982-1983. Studies of sea level trends depend primarily on accumulated tide gage data over many years. Spring tides are large semi-daily tides that occur twice a month near f new moons when the lunar and solar attr are superimposed. Perigean tides are large s ly tides that occur monthly when the m closest to the earth. There are also tropic ti perihelion tides. Obviously, tides will be par ly high when spring tides coincide with p tides, tropic tides, perihelion and so forth. are presented which furnish monthly and extreme high tide predictions for 1983 t 2000. The predictions in these tables will pr measure of reassurance to those concerne California's coastal zone and should be u the design of protective structures and othe al engineering projects. Tremendous high ti not predicted for the remainder of this c Nevertheless, the highest tides in the perio 1990 will be slightly higher than those winter 1982-1983 due to enhancement of th nal lunar constituents in the 1986-1990 pe the moon's node cycle. UPWELLING AND RIVER RUNOF SOURCES OF DISSOLVED NITROUS O TO THE ALSEA ESTUARY, OREGON,
Oregon State Univ., Corvallis. Coll. of Ocea phy.
M. A. de Angelis, and L. I. Gordon.
Estuarine, Coastal and Shelf Science, Vol. 2 4, p 375-386, April, 1985. 4 Fig, 4 Tab, 3 ONR contract N00014-79C-0004.

Descriptors: *Nitrous oxide, *Upwelling, *R *Alsea Estuary, *Oregon, Nitrates, Nitrites, fication, Floods, Estuarine environment, Dis gases.

Surface waters of Alsea Bay, an unpolluted on the Oregon coast, were analyzed for oxide, nitrate and nitrite on a weekly or bi basis during the summer of 1979. The estua found to be a variable source of N2O atmosphere. Large and rapid increases in th centrations of N2O, NO3(-), and NO2(-) oc at the beginning of the sampling period a attributed to the influx of nutrient-rich upw water into the estuary with the tide. The quent decline in concentrations of nitrate, and nitrous oxide over the remainder summer is attributed to a decrease in upw intensity, a decline in nitrification rates assimilatory nitrate reduction. Measurement trous oxide at six stations along the Alsea were also made in September and October and after the onset of the rainy season. Sa taken after flood conditions were establishe systematically 50% higher than pre-flood sa The data suggest that soil runoff results in el concentrations of N2O in rivers. (Autho stract)

M AND LONG-TERM INFLU-
THE IMMIGRATION OF POST-
NANA PRAWNS PENAEUS MER-

GUIENSIS, INTO A MANGROVE ESTUARY OF THE GULF OF CARPENTARIA, AUSTRALIA,
Commonwealth Scientific and Industrial Research Organization, Cleveland (Australia). Marine Labs.
D. J. Staples, and D. J. Vance.
Marine Ecology - Progress Series, Vol. 23, No. 1, p 15-29, 1985. 11 Fig, 7 Tab, 40 Ref.

Descriptors: *Shrimp, *Estuarine environment, *Migration, *Fish migration, *Gulf of Carpentaria, *Australia, *Norman River estuary, Growth stages, Larval growth stage, Animal behavior, Physicochemical characteristics, Water temperature, Salinity, Nutrients, Seasonal variation.

Postlarval Penaeus merguiensis de Man were sampled regularly at the mouth of the Norman River estuary in the south-eastern Gulf of Carpentaria, Australia, from 1975 to 1979. A grid of stations up to 10 km offshore from the estuary mouth was also occupied over a 24 h period during November 1978. In these offshore stations, postlarvae migrated vertically in the water column in response to changes in tidal height, rising to near the surface just below low tide. Postlarvae entered the estuary throughout the flood tide with a peak in abundance occurring at the time of maximum current, regardless of time of day or night. During the monsoonal wet season (Dec-Mar), when estuary salinities were lower, postlarvae occurred deeper in the water column. Over the 4 yr of sampling, immigration on a day-to-day basis was extremely variable but a consistent spring-neap tidal cycle could be demonstrated. More postlarvae immigrated during the spring-tide period than during the neaps, although the pattern was complicated by a larger peak associated with every second spring tide (27.32 d). Although difficult to separate from tidal phase changes, lunar changes per se appeared to be less important than the relation between tidal phase changes and timing of moonset and moonrise. Immigration was restricted to the warmer months between October and April each year, with a large pulse of recruits occurring usually in spring (Oct-Nov) and a less consistent pulse occurring in autumn (Mar-May). Inter-annual variations were also large and it was suggested that these year-to-year differences were related to the amount of rainfall recorded during the previous wet season (9 mo earlier) and the associated changes in salinity, temperature, nutrients and abundances of adult prawns. Over larger time scales, both size and developmental stage (number rostral spines) were directly related to postlarval abundance. Thus, postlarvae tended to be larger and more well developed during spring and autumn of each year, and were also larger during years of high immigration rates. Increased growth as well as survival in years following good rainfall and enrichment is suggested. (Author's abstract)

NUTRIENT REGENERATION AND OXYGEN CONSUMPTION BY SEDIMENTS ALONG AN ESTUARINE SALINITY GRADIENT,
Maryland Univ., Solomons. Chesapeake Biological Lab.
W. R. Boynton, and W. M. Kemp.
Marine Ecology - Progress Series, Vol. 23, No. 1, p 45-55, 1985. 7 Fig, 1 Tab, 65 Ref.

Descriptors: *Cycling nutrients, *Oxygen demand, *Sediments, *Estuarine environment, *Chesapeake Bay, *Sediment-water interfaces, Spatial distribution, Environmental gradient, Salinity gradient, Phosphorus, Nitrates, Nitrogen, Ammonium.

Nutrient fluxes and oxygen consumption (SOD) across the sediment-water interface were measured in situ along with vertical profiles of dissolved and particulate-phase nutrients in sediments and overlying water at 8 locations along the salinity gradient of Chesapeake Bay during spring and summer. Strong spatial and temporal patterns were evident. Highest rates of sediment NH4(+) regeneration and SOD occurred in summer at mid-salinity (12 to 17%) stations. Sediment fluxes of dissolved inorganic phosphorus (DIP) were always low, possibly due to relatively oxidized conditions in surficial sediments. Nitrate (NO3(-)) fluxes generally were directed into the sediments in spring and from the sediments during summer, and in both seasons fluxes were proportional to NO3(-) concentrations in overlying waters. Seasonal shifts in sediment O:N flux ratios suggest that denitrification may have been important in spring but not summer. Significant relations were inferred between C:N:P composition of suspended materials and surficial sediments and the magnitude and direction of sediment-water fluxes. Although accretion of particulate nitrogen in sediments was less than 6% of NH4(+) regeneration in the lower bay, it was similar to rates of NH4(+) flux in the low salinity region, suggesting that burial represents a significant sink for N in some estuarine zones. SOD constituted an important term in watercolumn O2 budgets at all stations (16-50% of total respiration), and sediment regeneration of NH4(+) was capable of supplying 13 to 40% of calculated phytoplankton N requirement, being more important during the summer period of higher productivity. (Author's abstract)

HYDROLOGY AND CHANGES IN THE NUTRIENTS AND PHYTOPLANKTON LEVELS IN GOAT ISLAND BAY, NORTHERN NEW ZEALAND,
Auckland Univ., Leigh (New Zealand). Marine Research Lab.
N. J. Taylor, and F. J. Taylor.
Internationale Revue der Gesamten Hydrobiologie, Vol. 70, No. 2, p 173-186, 1985. 12 Fig, 2 Tab, 15 Ref.

Descriptors: *Nutrients, *Phytoplankton, *Estuarine environment, *Goat Island Bay, *New Zealand, *Bays, Solar radiation, Nitrates, Land use, Environmental effects, Ammonia.

Quantitative phytoplankton samples were taken fortnightly from four stations in Goat Island Bay, northern New Zealand, and from one station in the inflowing creek, over the period June 1981 to August 1982. The nutrient levels at each station were also measured. The phytoplankton was similar in quantity and composition to that found in an earlier survey in 1966-69. No correlations were found between the phytoplankton densities and the nutrient levels. Significant correlations of the phytoplankton were obtained with radiation levels. This indicates that the phytoplankton populations are limited by light intensity and not by nutrient availability. The only significant change was a doubling of the dissolved nitrate levels in the sea, which appeared to be related to increased nitrate levels in the freshwater creek. It is suggested that the increase is due to an increase in the farming and recreational use of the catchment area. Nutrient levels in the creek were, except for ammonia, higher than in the sea. Some evidence is presented that the increase in the nitrate levels in the sea was associated with increased nitrate levels in the creek. (Collier-IVI)

S. Cloutier, and R. Cote.
Internationale Revue der Gesamten Hydrobiologie, Vol. 70, No. 2, p 187-201, 1985. 12 Fig, 33 Ref.

Descriptors: *Phytoplankton, *Salinity, *Fjord of Saguenay, *St. Lawrence Estuary, *Quebec, Diatoms, Stress, Seasonal variation, Environmental gradients.

The Saguenay Fjord is characterized by very high run-offs. The annual flow varies between 1200 and 4200 cu m/s. During the summer the surface salinity shows a sharp horizontal gradient (from 1 0/00 to 20 0/00). The surface phytoplankton, mainly

freshwater and even some euryhaline species, is submitted to salinity stress. Continuous culture experiments were conducted to study the susceptibility of this freshwater phytoplankton under different salinity conditions. Some pennate diatoms (dominant group) are found as relatively tolerant to salinity. Microflagellates have been found to be resistant to salinity up to 26 0/00. Chlorophyll concentrations and rates of primary production of those organisms are as high as those of the control. (Author's abstract)

TWO-DIMENSIONAL CALCULATION OF TIDE BY EXPLICIT WEIGHTED RESIDUAL METHOD - I SHIBUSHI BAY,
Kagoshima Univ. (Japan). Faculty of Fisheries.
H. Kikukawa, and I. Seo.
Memoirs of the Faculty of Fisheries, Kagoshima University, Vol. 33, No. 1, p 13-21, December, 1984. 12 Fig, 9 Ref.

Descriptors: *Tides, *Shibushi Bay, *Japan, *Predictions, *Biro Island, Tidal hydraulics, Winds, Water currents, Bays.

A two-dimensional explicit weighted residual method is applied to estimate the tidal residual flow of Shibushi Bay. Only the M sub 2 tide is taken into account. The effects of the ocean current, the wind stress, the river current, the bottom stress etc. were not considered. The water mass is found to be well conserved after the 7 periods of calculations. There appear in the tidal residual flow a clockwise circulation around Biro Island and an anti-clockwise flow at the south of Biro Island. In the time averaged equation of momentum, the advective term and the gravity term are balanced at the inner part of the bay; at the outer part of the bay, the advective term, the gravity term and the Coriolis term are balanced. The viscous term is only important around Biro Island. The phase delay of the water surface elevation is found to be negligible all over the bay. (Author's abstract)

USE OF THE RB/K RATIO TO EVALUATE POTASSIUM NUTRITION OF PEATLANDS,
Minnesota Univ., St. Paul. Dept. of Soil Science.
C. G. Buttleman, and D. F. Grigal.
Oikos, Vol. 44, No. 2, p 253-256, April, 1985. 1 Fig, 2 Tab, 14 Ref. NSF grant DEB 7922142, and Minnesota Agricultural Experiment Station project 25-54.

Descriptors: *Rubidium, *Potassium, *Peatlands, *Peatbogs, *Minnesota, Nutrients, Vegetation, Plant physiology, Bogs, Mosses, Wetlands.

The Rb/K ratio was determined in two classes of forested peatlands, raised and perched bogs, in northern Minnesota. These two classes of bogs are deficient in K, but differ somewhat in degree of deficiency and in source of K. Differentials were sought in the Rb/K ratio between the two classes of bogs. The ratio was significantly lower in the living vascular vegetation on the raised bogs, but significantly higher in the deep peat in those bogs. There was no difference in the ratio in the living moss and shallow peat between bogs in the two classes. The ratio was apparently affected by biological selectivity in K uptake by plants under low-K conditions. These results raise questions concerning use of this ratio in ecosytem studies. (Collier-IVI)

ROLE OF PHYTOPLANKTON IN THE DISSOLVED OXYGEN BUDGET OF A STRATIFIED ESTUARY,
Southern Water Authority, Otterbourne (England). Resources Planning Lab.
P. G. Soulsby, M. Mollowney, G. Marsh, and D. Lowthion.
Water Science and Technology, Vol. 17, No. 4/5, p 745-756, 1985. 9 Fig, 20 Ref.

Descriptors: *Test Estuary, *England, *Mesodinium, *Eutrophication, *Dissolved oxygen, Phytoplankton, Photosynthesis, Vertical migration, Mathematical models, Stratification, Estuarine environment, Chlorophyll a.

The Test Estuary situated at the head of Southamption Water, southern England was identified as likely to be subject to a series of developments which would require careful consideration of their impact on its water quality. Dissolved oxygen was identified as the most important parameter for consideration since the estuary carries a substantial run of salmon each summer. In the Test Estuary, the lowest dissolved oxygen levels followed a mid summer phytoplankton bloom, dominated by the ciliate Mesodinium rubrum. A numerical model was developed to calculate the water circulation, vertical mixing, dissolved oxygen and chlorophyll a. To obtain agreement between observed and predicted dissolved oxygen and chlorophyll a distributions, it was necessary to simulate a unique characteristic, the diurnal vertical migration of Mesodinium. Mesodinium is extremely motile; during the day the main concentration of Mesodinium is found between 1 and 3 m, but a substantial downward movement occurs just before dusk and within 30 minutes the bulk of the population is contained in the botton third of the depth. This position is maintained throughout the hours of darkness, but prior to dawn, a substantial movement towards the surface occurs. During the bloom period supersaturated oxygen levels are maintained in the surface layers. The bulk of the nighttime respiration takes place in the bottom layers of the water column which do not receive the compensating photosynthetic oxygen. This may lead to a depletion of the oxygen from the bottom layers as the bloom progresses. (Moore-IVI)

BEHAVIOUR OF SUSPENDED SEDIMENTS AND MUDS IN AN ESTUARY,
Iwate Univ., Morioka (Japan). Dept. of Civil Engineering.
T. Umita, T. Kusuda, Y. Awaya, M. Onuma, and T. Futawatari.
Water Science and Technology, Vol. 17, No. 6/7, p 915-927, 1985. 19 Fig, 2 Tab, 9 Ref.

Descriptors: *Suspended sediments, *Mud, *Estuaries, Shear stress, Tidal effects, Sediment erosion, Sedimentation, Flocculation, Simulation, Model studies.

The fundamental behavior of suspended sediments and muds was investigated using an annular flume with the condition of cyclically changed shear stress. The results from two series of experiments showed that particle sizes which participate in the variation of suspended sediments were restricted to smaller sizes of the material. It was also found that the cyclically steady state was finally attained with respect to the suspended sediments as the tidal cycle repeated. In that state the suspended sediments were subject to three phenomena: erosion; deposition with dispersed state; and deposition with flocculation. A simple model of the suspended sediments in an estuary was developed and its behavior in a model estuary was simulated by using the fluxes of erosion and deposition in the experiment. That model well described the variation of the suspended sediments and muds. (Author's abstract)

ROLE FOR A SIMPLE DISCRETE-T MODEL TO DESCRIBE DISPERSION IN ESTUARY,
Sydney Univ. (Australia). Dept. of Chemical E neering.
T. Wood.
Water Science and Technology, Vol. 17, No. p 991-1000, 1985. 2 Fig, 3 Tab, 9 Ref.

Descriptors: *Estuaries, *Dispersion, *Mathe cal models, Tidal effects, Salinity, Model stu Hawkesbury River, Australia, Model stu River flow.

A simple discrete-time model is proposed to scribe dispersion in an estuary, based on tida changes between neighboring segments. A pr dure for parameter estimation and model valida is described which can be implemented wi minimum of field measurements; and the app tion of the model is demonstrated with data lected from the Hawkesbury River system, Sydney, Australia. The results indicate that modelling procedure described is capable of ducing useful predictions of the response of sal distribution to changes in fresh water input tidal amplitude. The method could be most u in circumstances where limitations on experim resources preclude the undertaking of a more tailed investigation. (Author's abstract)

Velocity and salinity data collected during summer of 1983 in the Tyne estuary (England used to investigate the dominant mechanism the flux of salt and dispersion. The instantan salt flux arises mainly from the combinatio velocity fluctuation with the tidal mean sali and the instantaneous dispersion results almos tirely from the combination of vertical oscilla velocity and steady salinity. Of the net do stream salt flux, 92.4% is accounted for by river discharge. The non-tidal drift appears to most importance in the net upstream salt flux. estuary has a strong vertical salinity gradient due to the strong secondary flow, has a uni transverse gradient; thus, the dominant facto the longitudinal dispersion arises from the ver shear in the oscillatory tidal current. The dis sion coefficient is highly time-dependent within tidal cycle as well as a function of distance. importance of time-varying longitudinal dispe coefficients are demonstrated in a water qu model by using the sensitivity analysis. WATER RETENTION, TRANSMISSION AND CONTACT CHARACTERISTICS OF LUDAS SAND AS INFLUENCED BY FARMYARD MANURE,
Haryana Agricultural Univ., Hissar (India). Dept. of Soils.
S. Kumar, R. S. Malik, and I. S. Dahiya.
Australian Journal of Soil Research, Vol. 22, No. 3, p 253-259, 1984. 3 Fig, 3 Tab, 14 Ref.

Descriptors: *Sand, *Water retention, *Transmission, *Manure, Permeability coefficient, Contact angle, Irrigation effects, Soil water.

A low retention capacity for water and a high percolation rate are the two major soil physical problems encountered in managing sandy soils. The soil-water contact property is one of the important factors influencing the infiltration of water into soils. Experiments were conducted in which small cylinders were filled to a depth of 20 cm with a sandy soil to which farmyard manure had been added up to a maximum rate equivalent to 846 t/ha. The cylinders were set in the ground and kept moist. At the end of 10 months samples were taken for measuring water retention and saturated hydraulic conductivity as well as the rate of horizontal infiltration for 0.01 M CaCl2 and alcohol. An apparent contact angle was calculated from the last two measurements. Manure application caused a progressive increase in the volume of water retained at a given suction, together with a small increase in available water. Hydraulic conductivity was decreased. Cumulative horizontal infiltration of 0.01 M CaCl2 decreased markedly with increase in manure applied. This decrease is attributed mainly to an increase in the contact angle. Increased water retention at all pressure potentials with manure applications means an increased water storage capacity of the sand. Decreased hydraulic conductivity, penetration coefficient and infiltration rate with manure application mean coverage of relatively larger areas under surface irrigation with a given quantity of irrigation water in improved sand as compared to control sand. OPTIMIZATION OF A SPATIALLY VARIABLE RESOURCE: AN ILLUSTRATION FOR IRRIGATED CROPS,
Agricultural Research Organization, Bet-Dagan (Israel). Div. of Soil Physics.
E. Feinerman, E. Bresler, and G. Dagan.
Water Resources Research, Vol. 21, No. 6, p 793-800, June, 1985. 2 Fig, 2 Tab. 26 Ref, 3 Append.

Descriptors: *Optimization, *Crop yield, *Irrigation effects, Corn, Decision making, Water supply, Spatial distribution, Variability.

Economic optimization of a resource which is space dependent and displays irregular spatial variation was investigated. The resource (yield) of an entire field is regarded as a random variable which depends on a random function on the one hand, and a control variable on the other hand. The study focuses on the question of how economically efficient levels of relevant control variables may vary as a function of random spatial variability of resources, taking into account the decision maker's attitude to risk. A general approach to cope with the above question is developed, and the effects of uncertainty on the levels of the optimal control variables are investigated by comparing a deterministic case with two uncertainty levels of decision making: risk neutral and risk averse. Following the general methodology, expectation value and variance of average yield are first approximated by Taylor series expansion and then closed-form solutions are obtained for a specific, exponential, yield production function. Subsequently, the general analysis is illustrated for the example of irrigated corn, the only control variable being water quantity, and with corp yield a spatial random function in the plane. The results suggest that the impact of random soil properties on optimum level of water application might be substantial. Hence it is generally worthwhile to account for spatial variability in optimizing level of irrigation or similar control variables. (Author's abstract)

UNCERTAINTY ANALYSIS OF WATER RESOURCE USE IN DHORA RESERVOIR COMMAND AREA,
Govind Ballabh Pant Univ. of Agriculture and Technology, Pantnagar (India). Dept. of Agricultural Economics.
J. Kumar, and V. H. Sharma.
Indian Journal of Power and River Valley Development, Vol. 33, No. 11, p 397-400, November, 1983. 2 Tab.

Descriptors: *Dhora Reservoir command area, *India, *Water management, Rainfall, Crop yield, Irrigation efficiency, Nitrogen, Crop production, Rice, Wheat, Sugarcane.

The Dhora Reservoir command area comprises 42138 hectares in the districts of Nainita, Bareilly and Rampur (India). The objectives of the present study were to find out probability distributions of fortnightly rainfall; to estimate fortnightly inflow of water into Dhora Reservoir over time; to prepare an optimal water resource plan for the Dhora Reservoir command area at different probable water suppy levels; and to find out optimum long run water resource plan for the Dhora Reservoir command area. The present use of nitrogen in the command area is concluded to be below optimal levels. It should be increased to three times that of the existing level in order to obtain maximum crop production with the available irrigation water. According to the long run plan developed on the basis of uncertainty analysis with respect to rainfall and, in turn, availability of water in Dhora Reservoir, the area located in the Dhora command to paddy, wheat, sugarcane, 34.70, 35.90, and 24.52% of total cropped area respectively, should be changed to 35.04, 35.39, and 25.00% of the cropped area respectively. The local varieties of paddy should be grown in the entire paddy area if the supply level of nitrogen remains at the existing level. At increased supply levels of nitrogen, the entire paddy area should be occupied by high yielding varieties. The nitrogen and irrigation water used for different crops should be adjusted over time, after observing the actual rainfall situation. The adoption of long run plans along with adjustments in cultural practices is expected to increase crop production in the area by 46.99% at existing nitrogen supply levels and by 99.27% without nitrogen constraint over the existing level of production. To improve the productivity of the soils in the Kura-Araxin valley of Azerbaijan systematic investigations of the irrigational areas should be carried out. Irrigational soils with similar ecologic features should be categorized for appropriate exploitation.

In addition to the usual agricultural procedures, surveillance of the quality of irrigational waters, including suitable purification of wastewaters and application of local fertilizers, should be focused on. Long range cultivation under irrigational conditions should generate fertile soils with an increased productivity of cotton, grain, rice and perennial grass by 60-70%. (Erdelyi-IVI)

Descriptors: *Stochastic process, *Optimization, *Multireservoir networks, Hydroelectric power, Algorithms, Reservoirs, Electric powerplants, Cost analysis.

The objectives of the optimal operation of a hydrothermal generating system is to determine a generation schedule for each plant in the system that minimizes the expected operation cost for the planning period. The availability of limited amounts of hydroelectric energy, in the form of stored water in the system reservoirs, makes the optimal operation problem very complex because it creates a link between an operating decision in a given stage and the future consequences of this decision. A computational scheme that is able to determine at each stage the most economical generation decision for each plant of a hydrothermal system is presented. The algorithm is based on the stochastic extension of Benders decomposition and can be implemented from already existing operation models. The results can be used in the weekly or monthly generation scheduling activities in real-time operation. The algorithm supplies at each iteration an upper and lower bound to the optimal solution, allowing an efficient trade-off between computational effort and accuracy. The algorithm can accomodate any kind of stream-flow model because the transition probabilities at the bifurcations can be specified at will. A case study with four reservoirs was used to illustrate in detail the application of the algorithm. Its performance was further assessed with an example with 37 reservoirs. (Moore-IVI)

Descriptors: *Florida, *Lake Okeechobee, *St. Lucie County, *Water quality control, *Water supply development, Irrigation water, Runoff, Phosphorus removal, Flow-ways, Canals.

Canal 131 was intended to convey irrigation water supply to Martin and St. Lucie counties in Florida. The canal would be a direct access to Lake Okeechobee and would connect the lake to existing Canals 23-25 in St. Lucie County. Backflow would return surplus rainfall runoff to Lake Okeechobee from the St. Lucie County canals. The Canal 131 Flow-way Plan provides a flow-way area north of Canal 131 where surplus runoff could be diverted and detained. The intent of the flow-way plan is to create a seasonal wetland community for the removal of phosphorus from backflow into the lake. A method for sizing a flow-way to remove phosphorus from surplus rainfall runoff is presented. A 6.65 sq mi (17.22 sq km) flow-way with minimal additional management techniques is economically and environmentally desirable. The plan will protect groundwater supplies by returning captured surface runoff stored in Lake Okeechobee for irrigation water supply and reduce the need for obtaining irrigation requirements from groundwater sources. Diverting nontidal flows, which previously carried runoff into the St. Lucie Estuary, will improve surface water quality in the estuary, enhancing fish habitat. (Moore-IVI)

OPERATION AND EFFICIENCY OF AUTOMATICALLY OPERATING WEIR STRUCTURES - A CONTRIBUTION TO CLEANER WATERS,
Technische Univ. Braunschweig (Germany, F.R.). Leichtweiss-Inst. fuer Wasserbau und Grundbau.
E. Macke.
Water Science and Technology, Vol. 17, No. 6/7, p 1211-1221, 1985. 8 Fig, 6 Ref.

Descriptors: *Storm runoff, *Weirs, *Automation, *Storm sewers, Water quality control, Storm wastewater, Impounding head, Combined sewer overflows.

The automatically operating weir structures presented are simple, largely maintenance-free structures which, when used as control elements in storm overflows, offer considerable advantages over the fixed weir sills. Irrespective of the intensity of rainfalls, these weirs do not discharge any surplus water into the receiving water, unless a maximum possible water level has been reached, which is then maintained at a virtually constant level until the floods subside. The maximum possible water level, the so-called impounding head, will be determined in such a way that, on the one hand, the sewer capacity will be fully utilized, and, on the other, any undesirable backwater in the sewer system can be precluded. The weirs are not only suited for installation in new structures, but may also be integrated in existing ones. Time and cost consuming constructional measures can be dispensed with, as the weirs, owing to their configuration (they are composed of individual segments), can be passed through the existing manholes. They allow considerable additional sewer capacities to be activated, in particular in low-head sewer systems, so that the installation of high-cost retaining basins, which normally require a high degree of maintenance, can either be limited or dispensed with altogether. As the receiving water will be affected only when a given impounding head has been reached, the amount of combined sewage discharged can be reduced to a minimum. (Author's abstract)

DEVELOPMENT AND USE OF AN EMPIRICAL MODEL FOR DISSOLVED OXYGEN IN THE RIVER DON, ABERDEENSHIRE,
Water Research Centre, Stevenage (England).
J. S. Alabaster, J. C. Allan, and C. W. M. Sim.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2244-2247, 1985. 2 Tab, 9 Ref.

Descriptors: *Model studies, *Dissolved oxygen, *River Don, *Scotland, Biological oxygen demand, Benthos, Nutrients, Streamflow.

Dissolved oxygen (DO) levels in relation to biochemical oxygen demand (BOD) loading were predicted for the lower River Don (Scotland) using an equation derived from Streeter and Phelps (1925). During September 1981 the flow of the river was close to the 95th percentile value and the BOD load remained relatively constant; validation of the model was carried out for this period. A multiple regression of the BOD decay coefficient (per km) (k sub 1) on flow and temperature explained 87% of the variation in k sub 1. Splitting the data within the different flow bands to distinguish those that were associated with BOD loads that were either higher or lower than averaged showed that both k sub 1 and the respiration rate (oxygen demand) of growths attached to the bed of the stream (g/cu m/km) (R) increased with increase in load. The predicted DO for the validation period at one station was 5.7 mg/l; the observed DO was 5.1 mg/l. The observed BOD was slightly (1.3 mg/l) higher than predicted and the values of k sub 1 and R were also somewhat higher than those calculated for the years 1973-79. There was a reduction in k sub 1 with increase in flow, although low temperature coinciding with high flow was also a minor contributing factor. Loads also influenced k sub 1. The maximum values of R occurred not at the highest flows (7.6 and 8.7 cu m/sec), but at 6.6 cu m/sec, perhaps partly because low water velocity at low flow reduced the mass-flow of nutrients below that limiting the growth of benthic organisms. ECOLOGICAL WATER QUALITY POLICY: AN ATTEMPT AT CONCEPT CLARIFICATION AND A PLEA FOR THE USE OF BIOLOGICAL ECOSYSTEM PARAMETERS,
Ministerie van Welzijn, Volksgezondheid, en Cultuur, Amsterdam (Netherlands).
A. Goedmakers.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2277-2280, 1985. 10 Ref.

Descriptors: *Ecology, *Ecological effects, *Water quality criteria, Water quality standards, Policy making, Physicochemical characteristics, Water chemistry, Indicators, Bioindicators.

Definitions, parameters, and standards for an ecological water quality policy are discussed. An ecological water quality policy is a water quality policy based on the ecosystem, and is not necessarily directed toward improvement of water quality as it would be defined for human health or industrial use as is currently done. Ecological parameters are those that describe the ecosytem; physical, chemical, or biological parameters may be employed in setting ecological standards. Although biological parameters have not been as accepted in standard setting as physico-chemical ones, their properties for description of the ecosystem make them indispensable for an ecological water quality policy. Biological parameters lack many of the technical problems associated with physico-chemical standards, but it is unlikely that one biological standard will be universally applicable, hence a differentiated approach to standard setting will be necessary. USING SEVERAL INDICES FOR BIOLOGICAL ASSESSMENT OF WATER QUALITY IN RUNNING WATER,
Limburg Water Pollution Control Authority, Roermond (Netherlands).
H. H. Tolkamp.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2281-2286, 1985. 1 Fig, 1 Tab, 17 Ref.

Descriptors: *Bioindicators, *Water quality, *River Geul, *Netherlands, Assessments, Statistical analysis, Species distribution, Species composition.

Samples (113) were collected in the drainage area of the River Geul (The Netherlands), and 88 of them were used in a comparison of various biological indices for water quality assessment. The Trent Biotic Index, Indice Biotique (French Biotic Index), Indice de Qualite Biologique Globale, the Chandler score, Biological Monitoring Working Pary Score, Saprobic Index, Quality Index (K sub 135), Expanded Biotic Index, and modifications of some of these indices were all calculated for all samples, which had been obtained from lowland, upland, and spring or small stream locations. The resulting figures for each index were divided into 10 classes so that frequency histograms of the same number of intervals were obtained for all indices. Most of the sites used in the calculations had fairly good to good water quality; several indices were clearly inadequate for identifying the pollution level at the sites studied. Several gave an underestimation of water quality, and at least one (K-index) appeared to overestimate the quality of the stream waters. The use of 10-class histograms does not provide a means of obtaining absolute pollution levels, but creates a means of comparison from one sample to another. To know which level of water quality is the best achievable for each stream reach, it is necessary to know what the natural running water community for that site would look like. Most biotic indices or saprobic indices cannot be translated into each other. The right assessment system should be chosen, fit to be used under local conditions, with a well-defined achievable maximum or pollutional range. (Rochester-IVI)

Descriptors: *Bioindicators, *Aquatic plants, *Bacteria, *Germany (Federal Republic), *Nitrogen removal, Species distribution, Indicators, Species composition, Microorganisms.

Submerged macrophytes and denitrifying bacteria composition reflected pollutional level at four sites in West Germany. An oligotrophic well near Stuttgart-Busnau and three, increasingly eutrophic, natural ponds in the Rhine Valley (Baggersee - oligotrophic, Festungsgraben - mesotrophic, and Koenigsee - eutrophic) were chosen. Chara vulgaris, Potamogeton nodosus, and P. trichoides occurred only in Baggersee, whereas Ceratophyllum demersum, Hippuris vulgaris, Nuphar lutea, and Utricularia vulgaris were found abundantly in the mesotrophic and eutrophic ponds. Hottonia palustris and Hydrocharis morsus-ranae were found only in Koenigsee. In Koenigsee prototrophic denitrifying organisms (Acinetobacter-Moraxella-Alcaligenes spp) constitutued the main part of the denitrifying flora. Altogether, 92 denitrifying bacteria were isolated, and the qualitative determination confirmed the quantitative results. Pseudomonas fluorescens and Vibrio spp were more frequent in the oligotrophic well and Baggersee, whereas P. alcaligenes and Aeromonas spp were mainly distributed in Koenigsee. Assessment of rapid changes of pollution level by chemical parameters should be supplemented by bio-indicators, such as the submerged macrophyte and microbial group analyses used here. USE OF LIMNOCORRALS FOR PESTICIDE TOXICITY STUDIES: EFFECT ON ZOOPLANKTON COMPOSITION AND DYNAMICS,
Tel-Aviv Univ. (Israel). Inst. for Nature Preservation Research.
A. Gasith, and A. S. Perry.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2432-2436, March, 1985. 3 Fig, 1 Tab, 5 Ref. FAO/IAEA Contract No. 1724/R4/SD.

Descriptors: *Limnocorrals, *Bioindicators, *Zooplankton, *Pesticide toxicity, Pesticides, Toxicity, Parathion, Fish, Water pollution effects.

The potential use of small limnocorrals for pesticide toxicity studies was investigated. The experiment was carried out using eight PVC limnocorrals anchored in a fish pond. The experiment lasted 10 days, with parathion introduced on days 0 (100 mg), 3 and 6 (50 mg). The limnological conditions in the fish pond and the limnocorrals were typical of a highly eutrophic system in summer. The initial residue concentration of parathion in the treated limnocorrals averaged 25-30 ppb. Between applications, concentrations of parathion in the water rapidly declined to 40%, 11-21%, and 23%, of the initial concentration after the 1st, 2nd, and 3rd applications, respectively. In the absence of fish and no exposure to parathion the population of the cladoceran species in the limnocorrals increased 2-4 fold within 24 hours. Exposure to parathion caused elimination of the dominant cladoceran species and sharp increases in the rotifer populations, within 24 hrs. In the presence of fish the response in the two limnocorrals was not uniform. In one limnocorral the cladoceran population declined and disappeared after 5 days. In the other limnocorral the cladoceran population initially declined but recovered after 2 days and became dominant thereafter. A comparison of the zooplankton species composition and dynamics in the parathion-free limnocorrals and the fish pond revealed a pronounced containment effect. Small enclosures may be useful for evaluation of the toxic effect of chemicals in short term experiments only. (Baker-IVI)

SOME ASPECTS ON ALGAL TOXICITY TESTS WITH NATURAL PHYTOPLANKTON,
Jyvaeskylae Univ. (Finland). Dept. of Biology.
V. Eloranta, and L. Halttunen-Keyrilainen.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2463-2468, March, 1985. 3 Fig, 1 Tab, 18 Ref.

Descriptors: *Phytoplankton, *Phytotoxicity, *Algae, Finland, Bioassay, Seasonal variation, Physical properties, Chemical properties, Nutrients, Biomass, Species composition, Temperature effects.

A three year project was started at the beginning of 1983 in which natural phytoplankton samples were taken from surface waters monthly or bimonthly from a natural, slightly eutrophic pond in the town of Jyvaskyla, Finland. The sensitivity of the algal communities to toxic compounds was examined under various conditions. Seasonal differences were indicated in the resistance of the phytoplankton to toxic effluents. No significant correlation was detected between the toxicity response of the samples and their chlorophyll content or their photosynthetic rate. The biomass markedly affected the response of phytoplankton to toxic chemicals, as well as species composition and temperature. The response of the phytoplankton to shock-discharges should be studied only by short term tests, when the situation is most natural and less complicated concerning, for example, the effects of nutrients in the sample water. ROLE OF THE DAPHNIA BIOASSAY IN THE ASSESSMENT OF THE QUALITY OF EFFLUENT DISCHARGES,
Yorkshire Water Authority (England).
G. M. Morris, and F. T. Buckley.
Water Pollution Control, Vol. 83, No. 4, p 539-546, 1984. 1 Fig, 7 Tab, 11 Ref.

Descriptors: *Water quality, *Daphnia, *Bioassay, Toxicity, Biological properties, Monitoring, Trout.

There is a need for a reliable, effective and simple biological method for determining the suitability of an effluent discharge containing highly toxic often unknown chemicals. A bioassay using Daphnia magna has recently been adopted as a BSI Standard which is the first method described for the biological testing of water quality. The Daphnia bioassay has several advantages, compared to the use of fish, especially the ease of culturing the much smaller Daphnia and the consequent savings in space and cost. From a survey of the literature and data available it appears that Daphnia magna and rainbow trout are equally susceptible to a wide range of toxicants. A successful demonstration has been outlined in the use of the Daphnia bioassay in the monitoring and control of discharges from a toxic waste landfill site. The bioassay is an acute test and the effect of sub-lethal and chronic damage cannot be assessed. Moreover, the true effect of any particular toxicant in the environment requires detailed investigation and research. Finally, several suggestions are made regarding the use of the bioassay and Daphnia in general. In particular one important use could be as a condition for inclusion in consents for the discharge of effluent into inland waters or public sewers. (Baker-IVI)

DETERMINATION OF SELENIUM IN SEWAGE SLUDGE USING AN ACID-DIGESTION BOMB AND FLUORIMETRY,
North West Water Authority, Warrington (England). Western Div.
I. A. Fleet, and G. S. Taylor.
Water Pollution Control, Vol. 83, No. 4, p 562-568, 1984. 3 Fig, 5 Tab, 34 Ref.

Descriptors: *Selenium, *Sludge, *Acid digestion bomb, *Fluorimetry, Spectroscopy, Acid digestion, Pollutant identification, Industrial wastewater, Domestic wastewater.

Selenium concentrations have been determined in samples of sludge taken from the major sewage-treatment works in the Liverpool and West Lancashire (England) conurbation. A number of these treat significant amounts of industrial effluent in admixture with domestic sewage and a considerable range of industrial activity is undertaken in their drainage areas. The concentrations of selenium found were not high, being broadly in agreement with data previously reported. Overall the combination of bomb digestion and fluorescence spectroscopy proved successful. In particular the bomb performed safely (over fifty digestions per bomb without mishap) and was consistently capable of almost total digestion. The bomb digestion described could prove valuable in the preparation of sludge for the estimation of other determinands and as a reference method when assurance of complete digestion is desirable. As is frequently the case when adapting analytical techniques to the determination of trace species in sewage sludges, the main obstacle was found to be the effect of the matrix. EDTA was the most suitable complexing agent but the standard additions method was necessary to cope with variations in the sludge cation matrix. The least satisfactory aspect of the procedure was the demand on the analysts' time and the development of a better system of matrix control to obviate the need for standard additions would be worthwhile. FLUX USE FOR CALIBRATING AND VALIDATING MODELS,
Army Engineer Waterways Experiment Station, Vicksburg, MS. Environmental Lab.
J. H. Wlosinski.
Journal of Environmental Engineering, Vol. 111, No. 3, p 272-284, June, 1985. 10 Fig, 3 Tab, 11 Ref.

Descriptors: *Water quality, *Model studies, *Calibration, *Validation, Dissolved oxygen, Simulation, DeGray Lake, Arkansas.

Predicted flux, or process rates, must be considered along with predicted state variables when calibrating or validating water quality models. Concentrating only on changes of state variables and ignoring predicted fluxes could result in the implementation of inappropriate management strategies. To illustrate this, the Corps of Engineers' one-dimensional reservoir water quality model, CE-QUAL-R1, was calibrated using data collected at DeGray Lake, Arkansas. Initial predictions of dissolved oxygen, using coefficient values obtained from the literature, were not satisfactory. Evaluation of the flux predictions for oxygen showed which processes were most important in regulating dissolved oxygen, and showed those that were incorrect when compared to measured values. During the ensuing calibration simulations, as the flux predictions were brought more in line with measured values, the predictions of dissolved oxygen improved markedly. (Author's abstract)

SEARCH FOR ACID-FAST BACILLI IN BOTTLED MINERAL WATERS,
Pisa Univ. (Italy). Ist. di Igiene.
G. Caroli, E. Levre, G. Armani, S. Biffi-Gentili, and G. Molinari.
Journal of Applied Bacteriology, Vol. 58, No. 5, p 461-464, May, 1985. 1 Tab, 7 Ref.

Descriptors: *Mycobacteria, *Mineral water, *Bottled water, Bacterial analysis, Italy, Public health.

Samples of bottled mineral water sold in Italy in accordance with the law on microbiological standards were examined for the presence of acid-fast bacilli. Eighty-four samples were tested, 11 with added carbon dioxide and 73 without. Acid-fast bacilli were found in 1 of the former samples and in 8 of the latter, a total of 10.7%. The mycobacterial count was always very low (2-3 cfu/l) except for one sample which showed large numbers of Mycobacterium sphagni. This finding was not confirmed in two following samplings of the same water. The other acid-fast bacilli isolated were: M. gordonae (four strains), M. flavescens (one strain), M. phlei (one strain) and Nocardia sp. (two strains) in two samples of different water. These bacilli are not thought to be normal component of the waters but are the result of incidental contamination. The risk of infection from drinking such waters can be regarded as irrelevant in hospitalized or immunologically compromised subjects who face a greater risk when using tap water for drinking or washing. RAPID METHOD FOR THE ANALYSIS OF TRIHALOMETHANES IN WATER,
South Australia Engineering and Water Supply Dept., Salisbury. State Water Labs.
B. C. Nicholson, D. B. Bursill, and D. J. Couche.
Journal of Chromatography, Vol. 325, No. 1, p 221-230, May, 1985. 4 Fig, 4 Tab, 17 Ref.

Descriptors: *Trihalomethanes, *Water analysis, Gas chromatography, Electron-capture detection, Sample preservation, Halogenated hydrocarbons.

A rapid and precise method for the analysis of trihalomethanes (THMs) in water is described. Samples are extracted with methylcyclohexane and analyzed by gas chromatography using a short capillary column and electron-capture detection.

THMs elute with baseline separation in 1.25 min, and detection limits of 1 micro-g/l are readily achievable using 100-ml samples and 2 ml of solvent. Standards are prepared in the same way as samples by extraction of aqueous solutions to compensate for the relatively low extraction efficiencies which result from the low solvent to water ratio used. Ascorbic acid is a more effective sample preservative than sodium thiosulfate. (Author's abstract)

DETERMINATION OF TRACE AMOUNTS OF ORGANOPHOSPHORUS PESTICIDES AND RELATED COMPOUNDS IN SOILS AND SEDIMENTS USING CAPILLARY GAS CHROMATOGRAPHY AND A NITROGEN-PHOSPHORUS DETECTOR,
State Chemical Supervision Service, Soeborg (Denmark).
J. Kjolholt.
Journal of Chromatography, Vol. 325, No. 1, p 231-238, May, 1985. 5 Fig, 2 Tab, 18 Ref.

Descriptors: *Organophosphorus pesticides, *Sediment analysis, *Pollutant identification, Gas chromatography, Wastewater analysis.

A sensitive, selective and relatively precise method was developed for the determination of organophosphorus compounds in matrices with high contents of organic or biological material, and has been tested on soil and sediment samples. Homogenized samples are subjected to Soxhlet extraction with acetone-n-hexane and the extract is partitioned between methylene chloride and water. The extract of the combined methylene chloride phases is cleaned up by adsorption chromatography and analyzed by capillary gas chromatography using a nitrogen-phosphorus detector. Recoveries at the 10 ppb level are between 54.6 and 82.4% with standard deviations between 3.1 and 8.9%. Detection limits are between 95 and 220 ng/kg. With minor adjustments the method is applicable to wastewater and foodstuffs, for which the Soxhlet extraction step is not needed. The method is currently being used in a study of the dispersal of pollutants from a point source to a marine inlet. (Moore-IVI)

LEACHATE ATTENUATION IN THE UNSATURATED ZONE BENEATH LANDFILLS: INSTRUMENTATION AND MONITORING OF A SITE IN SOUTHERN ENGLAND,
Aspinwall and Co., Shrewsbury (England).
H. D. Robinson, and J. L. Lucas.
Water Science and Technology, Vol. 17, No. 4/5, p 477-492, 1985. 5 Fig, 4 Tab, 15 Ref.

Descriptors: *Groundwater pollution, *Leachates, *Landfills, *Monitoring, Water pollution sources, Attenuation blankets, Unsaturated zone, Waste disposal, Anaerobic conditions, Hydrogen ion concentration, Chlorides, Organic compounds, Temperature effects, Gases, England.

In the United Kingdom great reliance is placed upon the attenuation of contaminants which occurs as leachate seeps through intergranular unsaturated zones beneath landfill sites. At a site in Southern England, the landfill design incorporated an engineered, semipermeable attentuation blanket, using locally available calcareous sands and silt, emplaced to a minimum depth of 6 m above the water table. Installation of over 100 sampling and monitoring instruments within this unsaturated zone before waste disposal began in June 1982 made it possible to obtain water samples from the saturated and unsaturated zones, gas samples from the unsaturated zone, and to measure soil water pressure, electrical conductivity, and temperature in situ, at 3 monthly intervals since this date, to allow movement and attenuation of decomposition products of solid wastes to be monitored. The unsaturated zone rapidly became anaerobic as a result of migration of landfill gases through it, well in advance of any leachate front. The high buffering capacity of the calcareous sand/silt mixture prevented reduction in pH-values, and high concentrations of ammonia did not occur, probably as a result of cation exchange processes. Migration of other leachate constituents occurred, with raised concentrations of chloride and organic constituents detected after 15 months. The rate of migration varied significantly between individual sites. Based on the total volatile acids to chloride ratio, methane fermentation processes are active at least in some regions of the unsaturated zone, but their efficiency may suffer from the combined effects of direct toxicity of fatty acids and relatively low temperature. (Moore-IVI)

Descriptors: *Bacteriophage, *Wastewater analysis, *Bioindicators, Viruses, Salmonella, Industrial wastewater, Hospitals, Food-processing industry, F specific bacteriophage.

F specific RNA (FRNA) bacteriophages are attractive models for the study of the fate of animal viruses in water treatment processes and pure cultures (MS2, f2) have frequently been used in model experiments. The use of indigenous FRNA phages has been hampered by the lack of selective enumeration methods. Usually, bacteriophages in sewage are enumerated by counting the number of plaques produced in a lawn of an Escherichia coli host strain. Both somatic and F specific phages will contribute to the count. A simple and highly selective method, based on a specifically constructed host strain of Salmonella typhimurium (WG 49, phage type 3 Nalr (F'42 lac :: Tn5)), was developed. Counts on this host strain normally originate exclusively from F specific phages, because there are few somatic Salmonella phages in most sewage samples. FRNA phage counts from natural sewage samples using this host strain are more reliable and higher than those obtained on E. coli hosts. F specific bacteriophages were detected in all samples investigated in numbers ranging fro 50,000 pfu/ml. Data are presented on the and types of F specific phages in mixed do industrial sewage; in poultry pro wastewater and in hospital wastewater. The tial of F specific phages as water quality ind is discussed. (Author's abstract)

An enzyme calorimetric method, employing immobilized cholinesterase to detect harmful levels of organophosphorus and carbamate insecticides in water, is described. Immobilized cholinesterase activity was assessed automatically in a microcalorimeter by analyzing its catalytic efficiency in hydrolyzing a substrate solution which was passed over the enzyme at regular time intervals. A microcomputer was used to automate the procedure and for data acquisition. The inhibitory effects of three organophosphorus and two carbamate pesticides upon cholinesterase were studied in order to evaluate the efficacy of the technique. (Author's abstract)

BIOLOGICAL ASSESSMENT OF WATER QUALITY IN RUNNING WATER USING MACROINVERTEBRATES: A CASE STUDY FOR LIMBURG, THE NETHERLANDS,
Limburg Water Pollution Control Authority, Roermond (Netherlands). Dept. of Hydrobiology.
H. H. Tolkamp.
Water Science and Technology, Vol. 17, No. 17, p 867-878, 1985. 7 Fig, 1 Tab, 16 Ref.

Descriptors: *Invertebrates, *Bioindicators, *Water quality, *Limburg, *Netherlands, Species composition, Streams, Biotic index.

To obtain suitable biological methods for evaluating water quality several methods were applied to the macroinvertebrate composition of streams in the southern region of the province of Limburg (the Netherlands). After evaluation of the results through comparison followed by elimination of unsuitable methods (e.g. Trent Biotic Index, Indice Biotique, Indice de Qualite Biologique Globale) four methods remained promising: the Saprobic-index, the Quality-index, the BMWP-aspt and the Chandler-aspt. A further selection of methods must be carried out in combination with a typological classification of the streams concerned, including a description of the achievable range for each method. To this end more research in the field of stream typology is needed, especially for the province of Limburg with its high diversity of streams. (Author's abstract)

ENUMERATING INJURED COLIFORMS IN DRINKING WATER,
Montana State Univ., Bozeman. Dept. of Microbiology.
M. W. LeChevallier, and G. A. McFeters.
Journal of American Water Works Association, Vol. 77, No. 6, p 81-87, June, 1985. 3 Fig, 1 Tab, 105 Ref. EPA grant R807092.

Descriptors: *Bacterial analysis, *Bioindicators, *Coliforms, *Drinking water, Water quality control, Water analysis, Bacteria.

Injury to indicator bacteria can result from a variety of sources, including chlorine and other disinfectants, heat, freezing, sunlight, pH, transition metals, antagonistic plate count organisms, and possibly other undefined chemical and physical parameters. Many factors can influence injury, including time and temperature of exposure, strain of organism, physiological state, concentration of nutrients, neutralization technique dilutent and sample methodology. Effective alternative methods exist that are specifically designed for enumerating injured total and fecal coliforms. Operators and managers should be aware of the reality of injured coliforms. Injured indicator bacteria exist in every aquatic environment studied and may represent about half of the coliforms present. Utilities should perform parallel coliform analyses using m-Endo and m-T7 agars to assess the extent of occurrence of injured coliforms. Epidemiological investigations should be performed to further evaluate the role of stressed indicator bacteria in outbreaks of waterborne disease. (Baker-IVI)

TEST INSTRUCTIONS FOR MEASURING THE MICROBIAL METABOLIC ACTIVITY IN WATER SAMPLES,
Deutscher Verein des Gas- und Wasserfaches e.V., Eschborn (Germany, F.R.).
U. Obst.
Fresenius's Zeitschrift fur Analytische Chemie, Vol. 321, No. 2, p 166-168, May, 1985. 7 Ref.

Descriptors: *Water analysis, *Bacterial analysis, *Bacterial physiology, *Metabolism, *Enzymes, Enzymatic activity, Physiology, Chromophores, Catabolism, Chemical analysis.

Direct measurements of microbial metabolic degradation have previously been proven successful for testing influence of wastewater on surface water, describing the quality of water, analyzing groundwater, and biological treatment. Tests for measuring eight different enzymatic activities were developed; these enzymatic activities of the microbial metabolism in water can be measured after an addition of chromogenic substrates and their turnover. After the reaction the concentration of the chromophoric group proportional to the enzymatic activity is determined photometrically. If the molar value of the chromophore in the original substrate is known and the reaction is linear, the enzymatic turnover can be calculated in percent of conversion per liter and hour. With these biochemical methods, it is possible to determine enzyme activities concerning the catabolism of polymer substrates, di- and monomer fragments resulting from it, and finally energy-delivering metabolic activities. The enzymatic activity tests are suitable for use in a standard laboratory as a supplement to chemical and biological analyses; they do not call for extensive effort or expensive equipment. STATISTICAL EVALUATION OF AN INDUCTIVELY COUPLED PLASMA ATOMIC EMISSION SPECTROMETRIC METHOD FOR ROUTINE WATER QUALITY TESTING,
Geological Survey, Denver, CO.
J. R. Garbarino, B. E. Jones, G. P. Stein, W. T. Belser, and H. E. Taylor.
Applied Spectroscopy, Vol. 39, No. 3, p 535-541, May/June, 1985. 7 Fig, 10 Tab, 11 Ref.

Descriptors: *Spectroscopy, *Atomic emission spectrometry, *Atomic absorption spectrometry, *Molecular absorption spectrophotometry, *Inductively coupled plasma, *Emission spectroscopy, Metals, Trace metals, Water analysis, Chemical analysis.

In an interlaboratory test, inductively coupled plasma atomic emission spectrometry (ICP-AES) was compared with flame atomic absorption spectrometry and molecular absorption spectrophotometry for the determination of 17 major and trace elements in 100 filtered natural water samples. No unacceptable biases were detected. The analysis precision of ICP-AES was found to be equal to or better than alternative methods. Known-addition recovery experiments demonstrated that the ICP-AES determinations are accurate to between + or - 2 and + or - 10 percent; four fifths of the tests yielded average recoveries of 95-105%, with an average relative standard deviation of about 5%. INVERTEBRATE BIOASSAYS WITH NORTH SEA WATER SAMPLES. I. STRUCTURAL EF-

FECTS ON EMBRYOS AND LARVAE OF SERPULIDS, OYSTERS AND SEA URCHINS,
Biologische Anstalt Helgoland (Germany, F.R.)
K. Klockner, H. Rosenthal, and J. Willfuhr.
Helgolander Meeresuntersuchungen, Vol. 39, p 1-19, 1986. 5 Fig, 1 Tab, 33 Ref.

Descriptors: *North Sea, *Bioassays, *Invertebrates, *Ocean dumping, Immature growth stages, Oysters, Sea urchins, Polychaetes, Titanium dioxide, Sludge, Water pollution effects, Waste disposal.

The initial approach and the first results of bioassay techniques testing North Sea water samples from various dump sites in the laboratory are reported. Special attention is given to detailed methodological descriptions because of the importance of various handling procedures as contributors to experimental background variability. The usefulness of larval bioassay with sea urchins, oysters and polychaetes in future control and effects monitoring studies is discussed. A titanium dioxide dumping site was sampled immediately after dumping and 10 hr after dumping. Samples were also taken in the sewage sludge deposition area in the intervals between the usual dumping activities, regardless of the exact dumping schedule. The preserved bioassay test organisms were inspected microscopically to count percentages of normal larval hatch in test water samples, reference water samples and laboratory aged control water samples. A significant suppression of larval development of Pomatoceros triqueter in the trail water of the titanium dioxide dump site was noted while the development of sea urchin larvae was still affected in the 10 hr surface samples. Hatching of all test organisms in bottom-water samples from the center of the sewage sludge dump site was affected to different degrees when compared to reference areas about 4 km north or 6 km northwest of the dumping area. Further verification is needed to minimize experimental background variability of the bioassay and to enlarge the catalogue of suitable effects criteria. (Baker-IVI)

5B. Sources Of Pollution

DISTRIBUTION AND DECOMPOSITION OF LIGNOSULPHONATES IN LAKE PAIJANNE, CENTRAL FINLAND,
Jyvaeskylae Univ. (Finland). Inst. for Environment Research.
K. Granberg, and J. Granberg.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2254-2258, 1985. 1 Fig, 5 Tab, 12 Ref.

Descriptors: *Lignin, *Lignosulfonates, *Lake Paijanne, *Finland, *Fate of pollutants, Pulp and paper industry, Industrial wastewater, Pollution load.

Loading and distribution of lignin compounds in Lake Paijanne, Finland, were calculated for the 1960's, 1982, and predicted for 1985. The lake has received varying amounts of lignin in wastes from pulp and paper plants on its shore. It has a highly irregular shape, so individual basins were considered separately. Decomposition of lignin was calculated based on the equation: C = C sub o x 10 to the -kt power, where C = lignin loading (tons/day) as Na-lignosulfonates after time t, C sub o = original lignin loading (tons/day), k = the decomposition coefficient, and t = time in days. Three different decomposition coefficients were used: k sub 1 = 0.00131/day for the period 1-100 days, k sub 2 = 0.0004/day for the period 100-365 days, and k sub 3 = 0.0003 for the period 365-1,000 days. A computer program was used that calculated lignin loading of each basin in tons/day and the ligonsulfonate concentration (mg/l) using lignin loading from the pulp mill (tons/day), basin volume (cu m), and mean discharge as inputs. Calculated lignin loads within the 9 basins of the lake were much higher in the 1960's (58.5 tons/day, lignosulfonates 4.2-26.8 mg/l) than in 1982 (14.2-54.1 tons/day, lignosulfonates 1.0-3.3 mg/l), but the levels predicted for 1985 are somewhat higher (17.5-65.1 tons/day, lignosulfonates 1.1-6.9 mg/l), with exact levels depending on which of three discharge assumptions is used. The higher loadings are related to the start-up of a new plant at Aanekoski contributing 62 tons/day lignin load. The results calculated here represent the steady-state situation; predicted results must therefore be confirmed by actual results obtained 2-3 yr after the prediction was made. (Rochester-IVI)

MODIFICATION OF THE RELATIVE IMPORTANCE OF THE CARBON BALANCE IN A POLLUTED BROOK AFTER A PERIOD OF SPATE (MODIFICATION DE L'IMPORTANCE RELATIVE DES FLUX DE CARBONE D'UN RUISSEAU POLLUE APRES UNE PERIODE DE CRUE),
Savoie Univ., Chambery (France).
D. Fontvielle, and B. Cazelles.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2270-2276, 1985. 3 Fig, 1 Tab, 17 Ref.

Descriptors: *Carbon balance, *Stream pollution, *High flow, Pollution load, Invertebrates, Biomass, DNA, Carbon dioxide, Sedimentation, Precipitation, Organic matter.

During seven months (October 1981 to April 1982), the carbon balance of an organically polluted brook was followed from the measure of several parameters: benthic and water organic load, macroinvertebrate biomass, DNA, CO2 production of the sediment and emergences. The results are interpreted in relation to the precipitation and to the stream discharge. It appears that the role played by the biological processes is negligible compared to the rate of the waste input or to the rate of the sedimentation. (Author's abstract)

SELF-PURIFICATION WITH CONTROLLED REDOX CONDITIONS,
Bayreuth Univ. (Germany, F.R.). Lehrstuhl fuer Hydrologie.
T. Frevert, and I. Baumgartner.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2310-2313, 1985. 1 Fig, 1 Tab, 6 Ref.

Descriptors: *Oxidation-reduction potential, *Wastewater treatment, *Chemical oxygen demand, *Self-purification, Hydrogen ion concentration, Anoxic conditions, Water treatment, Dissolved oxygen.

Using a specialized apparatus and mixtures of domestic sewage and activated sludge, pe/pH feedback control was compared with no control for chemical oxygen demand (COD) removal. Redox intensity set points (pe sub 7, ie, referred to pH 7) ranged from 5.5 (full aeration) to -4.3 (no oxygen input). COD removal rates ranged from 10 to the -1.93 power per day under fully aerated conditions to 10 to the -3.12 power under completely anoxic conditions. When pe was feedback controlled so that O2 input was restricted to a certain set point, dissolved oxygen (DO) concentrations at all set points < or = 4.3 + or - 0.5 decreased immediately to zero, but corresponding COD removal rates remained in the same order of magnitude as with full aeration. Only with pe sub 7 < or = 0 (pH 7) did COD removal rates decline to 'anoxic' levels. pH was also feedback controlled. At pH = 6.0 + or - 0.2, COD removal rate was much lower corresponding to the CO2 accumulation at this pH. The economic advantage of O2 regulation becomes apparent when DO versus pe feedback control are compared. With the typical minimum DO feedback control condition of = 1 ppm, there would be a 0.07 kp per cu m per hr loss in oxygen feed. Control of the oxic self-purifying activity by pe feedback can be done at zero DO concentration, leading to maximal velocities of oxygen supply to DO-consuming microorganisms. (Rochester-IVI)

ASSESSMENT OF THE SIGNIFICANT PHYSICOCHEMICAL INTERACTIONS INVOLVED IN PESTICIDE DIFFUSION WITHIN A PESTICIDE-SEDIMENT-WATER SYSTEM,
Agricultural Research Service, Riverside, CA. Salinity Lab.
D. L. Corwin, and W. J. Farmer.
Chemosphere, Vol. 13, No. 12, p 1295-1317, 1984. 12 Fig, 1 Tab, 22 Ref. Water Resources Center project UCAL-WRC-W-485.

Descriptors: *Pesticides, *Diffusion, *Mathematical models, Sediment-water interfaces, Porous media, Adsorption, Hysteresis, Fate of pollutants, Physicochemical properties.

Because of the ability of soil to adsorb a variety of chemicals and the subsequent transport of the chemicals via erosion processes into aquatic systems, sediments of various water bodies have become repositories for many harmful chemicals. Using the explicit method of finite differences, a one-dimensional numerical model for the diffusion of pesticides through a sorbing porous medium under saturated conditions has been developed to assess the significant physical and chemical properties which influence the diffusion process in an aquatic system. Models were developed for the three different types of adsorption generally encountered in a sorbing porous medium: linear, Freundlich and Langmuir. An additional model deals with hysteresis for the three adsorption situations. The models show that the degree to which a pesticide is retained by a sediment is determined by the sediment's adsorptive capacity, strength of adsorption, porosity and bulkdensity, as well as the temperature of the aquatic system, the chemical nature of the pesticide and the pesticide's aqueous solution diffusion coefficient. The pollution of overlying water bodies by the diffusion of pesticides from sediments is a potential problem due to the toxic effect of very low levels of some pesticides to aquatic life forms. A sediment with a high adsorptive capacity and a high strength of adsorption would release pesticides to the water at a slower rate and in lower amounts, posing less of a potential hazard to fish. Highly organic sediments which could retain high levels of adsorbed pesticide material could pose a threat to filter-feeding organisms which rely upon organic matter at the sediment-water interface as a food source. MODULAR CONTAINERS FOR MICROCOSM AND PROCESS MODEL STUDIES ON THE FATE AND EFFECTS OF AQUATIC CONTAMINANTS,
Columbia National Fisheries Research Lab., MO.
J. N. Huckins, J. D. Petty, and M. A. Heitkamp.
Chemosphere, Vol. 13, No. 12, p 1329-1341, 1984. 3 Fig, 1 Tab, 15 Ref.

Descriptors: *Microcosms, *Fate of pollutants, *Model studies, Ecosystems, Lentic environments, Simulation, Microbial degradation, Fonofos, Trifluralin, Carbon radioisotopes, Mass balance.

Container modules are described for the laboratory simulation of selected processes and ecosystems that are representative of lentic environments. Emphasis is placed on design features permitting mass balance accountability of contaminant residues and procedural cautions required for the proper use of the described systems in environmental simulations. Experiments on the efficiency of container modules for microbial mineralization studies were conducted using C-14 labeled NaHCO3, and acidification resulted in a C-14-CO2 recovery of 97.3 +/- 4.7%. The trapping efficiency of pesticides volatilized from water and glass surfaces was investigated using the same module and the mean recoveries of C-14-fonofos and C-14-trifluralin were 114.2 +/- 3.2% and 95.2 +/- 3.5%, respectively. The mass balance capabilities of the system was also demonstrated for extended microcosm exposures to C-14-trifluralin. (Author's abstract)

LEACHABILITY OF CARBON-14-LABELLED 3,4-BENZOPYRENE FROM COAL ASH INTO AQUEOUS SYSTEMS,
Hoofdgroep Maatschappelijke Technologie TNO, Delft (Netherlands).
A. C. Besemer, and J. Kanij.
Chemosphere, Vol. 13, No. 12, p 1343-1351, 1984. 5 Tab, 18 Ref.

Descriptors: *Benzopyrene, *Leaching, *Coal ash, Polycyclic aromatic hydrocarbons, Carbon radioisotopes, Tracers, Hydrocarbons, Aromatic compounds, Water pollution sources.

Combustion products such as fly ash from coal-fired furnace and municipal incinerators may contain harmful substance, such as polycyclic aromatic hydrocarbons (PAH). In contact with aqueous systems, leaching of these substances can lead to contamination of the environment. The leachability of polycyclic aromatic hydrocarbons from coal ash into aqueous systems was studied. Carbon-14-labeled 3,4-benzopyrene (BaP) was deposited on coal fly ash at about 10 micro-g/g ash. The desorption of BaP was measured using aqueous solutions of acetone and methanol as extractants and liquid scintillation counting as detection method. In all cases the C-14 recovery was incomplete. Using water as extractant, C-14 recoveries of about 1% were found. In the presence of a non-ionic surface active agent the C-14 recovery was enhanced significantly. In order to assess the potential hazard of disposed fly ash with respect to the leaching of toxic substances it is necessary to develop testing methods with real representative adsorbents under realistic aqueous waste disposal conditions. FATE AND EFFECTS OF PENTACHLOROPHENOL IN HARD- AND SOFT-WATER MICROCOSMS,
Environmental Research Lab., Athens, GA.
D. L. Brockway, P. D. Smith, and F. E. Stancil.
Chemosphere, Vol. 13, No. 12, p 1363-1377, 1984. 2 Fig, 3 Tab, 16 Ref.

Descriptors: *Pentachlorophenol, *Microcosms, *Fate of pollutants, *Water pollution effects, Hardness, Nutrients, Silica, Oxygen, Chlorophenols.

Microcosms were used to investigate the influence of water hardness on the fate and effects of pentachlorophenol (PCP). The laboratory ecosystems developed similarly in both hard and soft water with only minor differences in structure and function. After exposure to PCP, system structure showed minor evidence of impact, but the results were similar in both hard and soft water. Dissolved silica was the only nutrient that responded differently in hard and soft water. It was the only nutrient significantly influenced by PCP, and may be a sensitive parameter for detecting low level effects of toxicants in certain systems. Differences between hard and soft water were detected in net oxygen production when the systems were exposed to 4 mg/l PCP. (Moore-IVI)

MATHEMATICAL SIMULATION OF THE CONVERSION AND TRANSPORT OF NUTRIENTS IN DRAINAGE AREAS - A REVIEW OF THE LITERATURE (MATHEMATISCHE SIMULATION VON NAHRSTOFFUMWANDLUNG UND -TRANSPORT IN EINZUGSGEBIETEN-LITERATURUBERSICHT),
Akademie der Wissenschaften der DDR, Berlin. Inst. fuer Geographie und Geooekologie.
V. Mohaupt, and G. Wernecke.
Acta Hydrochimica et Hydrobiologica, Vol. 11,

No. 6, p 609-621, 1983. 65 Ref.

Descriptors: *Mathematical models, *Simulation, *Nutrients, *Reviews, Nitrogen, Phosphorus, Solute transport, Runoff, Infiltration, Sediment erosion, Adsorption, Desorption.

Models used for mathematical description of nitrogen and phosphorus transport are outlined for various components of runoff; transport of nutrients in the process of runoff formation and concentration, infiltration and runoff within soil, surface runoff, and transport in receiving water. For surface runoff the Universal Soil Loss Equation is used frequently as the starting point for modeling, as well as for calculating sediment impulse loads. Adsorption and desorption are taken into account by their respective isotherms. Models from agriculture are used for representing soil nutrient balance, whereas for transport in receiving water, regressions on flow and deterministic models of nutrient conversion are applied. In all models the empirical share is still very high, and the model checking has often failed due to insufficient measured data. (Author's abstract)

ELIMINATION OF NUTRIENTS IN THE ROZKOS-RESERVOIR,
Prague Dept. of Water Technology and Environmental Engineering (Czechoslovakia).
J. Maixner, and V. Sladecek.
Acta Hydrochimica et Hydrobiologica, Vol. 11, No. 6, p 657-665, 1983. 3 Fig, 5 Tab, 17 Ref.

Descriptors: *Nutrients, *Rozkos Reservoir, *Czechoslovakia, Reservoirs, Fate of pollutants, Organic compounds, Nitrogen, Phosphorus, Iron, Bacteria.

The reservoir, having a volume of 76 cu hm, a surface area of 1001 ha and a maximum depth of 17 m, is divided by a dam into two parts. Half of the upper part with an area of 200 ha is densely covered by macrophytes (Elodea, Potamogeton). The three main tributaries with 2.6 cu m/s on an average are highly polluted and show alpha-meso-saprobic conditions. The reservoir is investigated between September and March in its longitudinal section at eight stations. The organic load and the total solids show a total decrease by 60% and 66%, respectively, and 70% of the selfpurification occurs in the upper, separated part of the reservoir. In the same way, also the total nitrogen is reduced, whereas the total phosphorus is reduced already in the upper part of the reservoir by 71%, then decreasing to 21% in the second part of the reservoir. With phosphorus, in addition to the biological elimination, precipitation by the dissolved iron also occurs; the iron concentration is reduced by 44 or 76%, respectively. The bacteriological load of water improved by two to three orders of magnitude. (Author's abstract)

Descriptors: *Degradation, *Fluorotensides, *Surfactants, Tensides, Fate of pollutants, Biochemical degradation, Surfactants, Detergents.

In continuation of a publication on the behavior of fluorotensides in aqueous solution there were tested four selected fluorotensides, among them a nonionononic ethoxylated substance and three anionactive substances, in two different types of equipment with respect to their biochemical degradability. The BOD5, the potassium permanganate consumption, the dry matter contents and the loss on ignition as well as the dehydrogenase test were used as parameters for judging the degradation behavior. In all the four cases a high biochemical stability was found, so that they must be classified into the group C 'biochemically not degradable or difficult to degrade' in agreement with the results found, according to the water pollutants catalogue. Descriptors: *Mathematical models, *Aquifers, *Water quality, Differential equations, Solute transport, Model studies, Free water, Groundwater movement, Dispersion, Path of pollutants.

A model is described for the relation between water quantity and water quality in the aquifer with the diffuse substance input by the gravitation water being taken into account. The model is based on a partial differential equation of the second order for a flow pipe. For constant transport parameters, a sink of the kinetics of the first order and a time-dependent source term an exact analytical solution is presented and explained by a model. At a diffuse substance input, the dispersion has only a slight influence on the transport of substances contained in water. Potential applications of these solutions to different problems are mentioned. (Author's abstract)

The potential of seven septic tank installati the Perth (Western Australia) metropolitan contribute phosphate to the groundwater v vestigated. The phosphate concentration in t solution below the soak wells and leach drai measured using immiscible displacement an pared with the phosphate concentration water flowing into the systems. The pho sorbing properties of the subsoils were mea and these were found to vary up to 100-fold the same profile. A very strong correlatio established between a laboratory measure ability of the soil to sorb phosphate and the phate sorbed in the soil profile below leach and soak wells. The correlation held only fo systems for which little further phosphat removed by reaction with the soil, and the phate in the soil solution was at or near the concentration as the phosphate in the effluen a system receiving water from the bathroom dry and kitchen the phosphate concentratio as low as 8 micro-g P/mol. For a system rec water from a toilet only, the concentration high as 29 micro-g P/ml. In systems rec water from both sources the values were in diate. For systems that had been installed fo than a few years, the concentration of phos in the soil water down to 6 m below the soa and leach drain was similar to that in the e being discharged into the soil. nal steady-state turbulent-diffu-
lved by a separation-of-variables
to a Sturm-Liouville eigenvalue
ral solution, for arbitrary veloci-
distributions, is shown to be in the form of an eigenfunction expansion. For a steady uniform flow in a wide, open channel the velocity distribution in the vertical is well approximated by a logarithmic lay and the diffusivity distribution is approximately parabolic. For these distributions the power-series solution technique for ordinary differential equations is used to determine the eigenfunctions and eigenvalues. The solution is compared with the standard solution that Holley, Siemans and Abraham (1972, J. Hydraul. Res. 10, 27-57) obtained for a uniform velocity and diffusivity distribution. Experimental results are presented, and these show that (1) the use of the correct velocity and diffusivity distribution results in a significant improvement in the agreement between experiment and theory; and (2) close to the source the fluctuations of concentration are of the order of the mean values. WHEN AND WHERE TO PUT A DISCHARGE IN AN OSCILLATORY FLOW,
Cambridge Univ. (England). Dept. of Applied Mathematics and Theoretical Physics.
R. Smith.
Journal of Fluid Mechanics, Vol. 153, p 479-499, April, 1985. 7 Fig, 13 Ref, 1 Append.

Descriptors: *Path of pollutants, *Oscillatory flow, *Mathematical equations, Flow, Discharge, Mathematical models, Dispersion, Estuaries.

Exact results are obtained for the centroid and longitudinal variance of a passive contaminant distribution at large times after an instantaneous discharge in an oscillatory flow in a straight channel of constant cross section. The precise timing and cross stream position of the discharge have a substantial and persistent influence. When and where to put a discharge in an oscillatory flow so that the spread of contaminant at large times is maximized (and the concentration is minimized) is considered. In an oscillatory flow the optimal location for a discharge will be away from the center or the sides. When the flow is oscillatory the contaminant is swept back and forth along the channel, so any time advantage is annulled. An important practical point is that real discharges are not passive. Near field momentum and buoyancy effects tend to augment the transverse mixing. The actual contaminant cloud well be wider than a passive cloud, and the effective time of discharge is earlier than the actual discharge time. The general principles are illustrated using a simple mathematical model of contaminant dispersion in a vertically well-mixed estuary of parabolic cross-section. (Baker-IVI)

RATE OF PRECIPITATION OF FERROUS IRON AND FORMATION OF MIXED IRON-CALCIUM CARBONATES BY NATURALLY OCCURRING CARBONATE MATERIALS,
Western Australian Inst. of Tech., South Bentley. School of Applied Chemistry.
J. E. Wajon, G.-E. Ho, and P. J. Murphy.
Water Research, Vol. 19, No. 7, p 831-837, 1985. 3 Fig, 4 Tab, 22 Ref.

Descriptors: *Fate of pollutants, *Iron, *Carbonates, *Chemical precipitation, Limestone, Calcite, Aragonite, Siderite, Supersaturation, Industrial wastewater, Wastewater pollution, Land disposal, Groundwater pollution.

An acidic iron-rich effluent produced by an industry in the southwest of Western Australia is disposed of by seepage through carbonate-rich sand dunes. The soluble iron content of the effluent was reduced from 6 g/l to less than 60 mg/l within several hundred meters of the disposal area. In order to determine what occurs under these conditions, an iron sulfate containing wastewater was reacted with aragonite, calcite and a variety of limestones and limesands pH values near 6 in an atmosphere of carbon dioxide. Siderite (ferrous carbonate) and a calcium siderite containing 10 mol% calcium were the only iron-containing products detected by X-ray diffraction, and accounted for substantially all the iron removed from solution. Calcium siderite was the major product and constituted between 50 and 100% of the iron containing product. The rate of precipitation of iron was proportional to the square of the supersaturation of the solution with respect to siderite, and increased with increase in pH and alkalinity. Precipitation occurred at different rates with different carbonate materials, tending to increase with increasing proportion of aragonite in the material. Precipitation did not occur in suspensions of calcite and was slow even in suspensions of aragonite where equilibrium was not reached within 40 days. The frequent occurrence of groundwaters apparently supersaturated with respect to siderite may be due either to slow precipitation of siderite, or to equilibrium of the groundwater with respect to a more soluble calcium siderite. The minerals present in an aquifer should be identified before conclusions on the saturation state of a groundwater with respect to siderite are made. (Moore-IVI)

Descriptors: *Fate of pollutants, *Model studies, *Solute transport, Sorption, Soils, Mathematical models, Porous media, Chemical equilibrium.

Sorption processes that occur during reactive solute movement through porous media can be modeled using either an equilibrium or kinetic approach. Because of the resulting conceptual and mathematical simplification, many transport models assume local chemical equilibrium is valid for describing sorption reactions. This paper presents quantitative criteria to assess the validity of the local equilibium assumption for one-dimensional, steady flow through homogeneous soils. A method is described whereby formulas for solute breakthrough curve time moments can be determined without knowledge of the analytical solution to the mass transport model. This method is applied to several commonly used nonequilibrium formulations as well as the standard linear equilibrium model. The formulations considered include both the physical nonequilibrium models where the sorption rate is controlled by diffusive solute transfer between mobile and stagnant fluid zones and the chemical nonequilibrium models where the overall sorption rate is governed by the rate of reaction at the soil-solution interfaces. Criteria for local equilibrium to be valid are derived by comparing the time moment formulas for the nonequilibrium and equilibrium models. These criteria explicitly show that basic system parameters (e.g., seepage velocity, dispersion coefficient, distribution coefficient, sorption rate, boundary conditions) have a significant influence on the attainment of local equilibrium. GROUND-WATER CONTAMINATION IN SILICON VALLEY,
California Regional Water Quality Control Board, Oakland. San Francisco Bay Region.
A. Olivieri, D. Eisenberg, M. Kurtovich, and L. Pettegrew.
Journal of Water Resources Planning and Management, Vol. 111, No. 3, p 346-358, July, 1985. 7 Fig, 2 Tab, 6 Ref.

Descriptors: *San Francisco Bay Area, *California, *Groundwater pollution, Water pollution sources, Soil contamination, Solvents, Underground tanks, Corrosive substances, Fuel, Wastewater, Regulations.

In the southern San Francisco Bay Area (California), a state regulatory agency carried out a questionnaire survey to determine the locations and characteristics of underground chemical storage and handling facilities at industrial sites in the area. Sampling of soil and ground water were required at sites where underground tanks containing sol-

vents were reported. The survey identified 1,692 tanks at 388 sites. The largest fraction were pretreatment sumps for industrial wastewater, followed by fuel tanks, solvent tanks, and tanks containing corrosives. Solvent tanks were reported at 96 sites. Subsurface investigations resulted in discovery of soil or ground water contamination (or both) at 75 of the 96 sites with solvent tanks. Further investigations and remedial actions are underway at these sites, and new regulations have been adopted at the state and local levels to prevent future release of industrial chemicals into soil and ground water. ARSENIC, BARIUM, GERMANIUM, TIN, DIMETHYLSULFIDE AND NUTRIENT BIOGEOCHEMISTRY IN CHARLOTTE HARBOR, FLORIDA, A PHOSPHORUS-ENRICHED ESTUARY,
Florida State Univ., Tallahassee. Dept. of Oceanography.
P. N. Froelich, L. W. Kaul, J. T. Byrd, M. O. Andreae, and K. K. Roe.
Estuarine, Coastal and Shelf Science, Vol. 20, No. 3, p 239-264, March, 1985. 6 Fig, 5 Tab, 75 Ref.

Descriptors: *Arsenic, *Barium, *Germanium, *Tin, *Dimethylsulfide, *Nutrients, *Biogeochemistry, *Charlotte Harbor, *Florida, Peace River, Estuaries, Salinity, Phosphates, Nitrates, Silica, Water pollution sources, Eutrophication, Diatoms, Fate of pollutants.

Concentrations of dissolved nutrients (NO3, PO4, Si), germanium species, arsenic species, tin, barium, dimethylsulfide and related parameters were measured along the salinity gradient in Charlotte Harbor (Florida). Phosphate enrichment from the phosphate industry on the Peace River promotes a productive diatom bloom near the river mouth where NO3 and Si are completely consumed. Inorganic germanium is completely depleted in this bloom by uptake into biogenic opal. The Ge/Si ratio taken up by by diatoms is about 0.0000007, the same as that provided by the river flux, confirming that silceous organisms incorporate germanium as an accidental trace replacement for silica. Monomethylgermanium and dimethylgermanium concentrations are undetectable in the Peace River, and increase linearly with increasing salinity to the seawater end of the bay, suggesting that these organogermanium species behave conservatively in estuaries, and are neither produced nor consumed during estuarine biogenic opal formation or dissolution. Inorganic arsenic displays slight removal in the bloom. Monomethylarsenic is produced both in the bloom and in mid-estuary, while dimethylarsenic is conservative in the bloom but produced in mid-estuary. The total production of methylarsenicals within the bay approximately balances the removal of inorganic arsenic, suggesting that most biological arsenic uptake in the estuary is biomethylated and released to the water column. Dimethylsulfide (DMS) increases with increasing salinity in the estuary and shows evidence of removal, probably both by degassing and be microbial consumption. An input of DMS is observed in the central estuary. The behavior of total dissolvable tin shows no biological activity in the bloom or in mid-estuary, but does display a low-salinity input signal that parellels dissolved organic material, perhaps suggesting an association between tin and dissolved organic matter. Barium displays dramatic input behavior at mid-salinities, probably due to slow release from clays deposited in the harbor after catastrophic phosphate slime spills into the Peace River. SEA-SURFACE MICROLAYER METALS ENRICHMENTS IN AN URBAN AND RURAL BAY,
Battelle Pacific Northwest Labs., Sequim, WA. Marine Research Lab.
J. T. Hardy, C. W. Apts, E. A. Crecelius, and N. S. Bloom.
Estuarine, Coastal and Shelf Science, Vol. 20, No. 3, p 299-312, March, 1985. 7 Fig, 1 Tab, 48 Ref.
DOE DE-AC06-76RLO 1830.

Descriptors: *Microlayers, *Metals, *Water pollution sources, *Bays, Urban areas, Lead, Zinc, Copper, Cadmium, Iron, Atmospheric deposition, Coastal waters, Marine environment.

The sea-surface microlayer is an important interface between the atmosphere and ocean and a collection point for many anthropogenic materials including potentially toxic metals. A glass plate sampler sampler was developed to collect the upper 30 to 55 micrometers of the sea surface. Samples of the microlayer and subsurface bulk water from an urban and rural bay were analyzed for concentrations of Pb, Zn, Cu, Cd, and Fe. Metal concentrations in both the microlayer and bulk water were generally 2 to 15 times greater in the urban than in the rural bay. Concentrations of metals in the microlayer of both bays averaged 6 to 65 times greater than those in the bulk water. In the urban bay, microlayer concentrations of Pb, Zn and Cu from 10 to > 100 micro-g/l were common. Measured microlayer metals concentrations agree well with those predicted from atmospheric deposition rates using a previously derived empirical model developed from laboratory microcosm studies. Further work will be required to determine whether or not these high microlayer metal concentrations contain significant biologically available fractions which could impact fisheries recruitment of larval icthyoneuston. (Author's abstract)

FLUXES AND RESIDENCE TIMES OF HYDROCARBONS IN THE COASTAL MEDITERRANEAN: HOW IMPORTANT ARE THE BIOTA,
International Lab. of Marine Radioactivity, Monaco-Ville (Monaco).
K. A. Burns, J.-P. Villeneuve, and S. W. Fowler.
Estuarine, Coastal and Shelf Science, Vol. 20, No. 3, p 313-330, March, 1985. 3 Fig, 6 Tab, 46 Ref.
NSF grant OCE 7923321.

Descriptors: *Hydrocarbons, *Fate of pollutants, *Mediterranean Sea, *Biota, Particulate matter, Chlorinated hydrocarbons, Petroleum products, Zooplankton, Primary productivity, Microlayers, Solute transport, Sediments, Marine environment.

Settling particles collected in semi-permanent particle interceptor traps (PITs) moored at 100 m depth in a water column of 250 m at a distance of 2 km from the Monaco coast in the north western Mediterranean were analyzed for petroleum and chlorinated hydrocarbons. Time series observations of material collected between 1979 and 1982 showed that vertical mass and organic contaminant fluxes varied seasonally by an order of magnitude and corresponded with general cycles of zooplankton biomass and primary productivity in surface waters. Analyses of surface seawater including surface microlayer, dissolved and particulate phases are reported along with data from zooplankton, fecal material, and sediments collected near the trap station. Settling particles displayed two predominant patterns of petroleum hydrocarbons similar to the patterns of both 'dissolved' and 'particulate' hydrocarbons seen in surface seawater. Residence times of hydrocarbons in surface waters were computed according to recent partitioning models and compared with those calculated from the fluxes of actually settling particles and from sediment data. PCB fluxes calculated from sediment and settling particles averaged 2 to 4 ng/sq cm/yr with good agreement between data bases. Petroleum fluxes on settling particles averaged 8 micro-g/sq cm/yr but fluxes based on sediment concentrations showed that 90% of the petroleum hydrocarbons transported to depth were degraded before incorporation into compacted sediments. By evaluating fluxes and residence times with three independent data bases it is concluded that the biota are effective in transporting both particulate and dissolved organic contaminants to ocean sediments. Furthermore, the residence times of these materials in surface waters do not vary as much as would be predicted on the basis of their widely differing solubilities. (Author's abstract)

ygen balance, *Teltow Canal, wer Plant, *Berlin, *Germany), Thermal pollution, Water pol- e of pollutants, Chemical reac-

The Teltow Canal in Berlin (West) has received the effluents of 4 sewage treatment plants, the storm water runoff from about 110 sq km of urban area and the heat discharge from three big power plants. A long term measuring program served data on water quality of the canal. The continuously registered O2-concentrations and temperatures were utilized for the calculation of a temperature coefficient for oxygen consumption. Comparing differently heated parts of the canal throughout the year, we found extremely high coefficients with a mean value of 1.34/C for 1982. Rapid changes in temperature during winter and spring (up to 10 C) resulted in the highest coefficients, which could be interpreted as the activation of additional O2-consuming processes (e.g, nitrification in winter). Measures for a more efficient sewage treatment and for the restoration of the oxygen budget are discussed. (Author's abstract)

DIFFUSION COEFFICIENT EVALUATED FROM THE DISTRIBUTION OF NONCONSERVATIVE MATERIAL (IN JAPANESE),
Kagoshima Univ. (Japan). Faculty of Fisheries.
H. Ichikawa, and M. Chaen.
Memoirs of the Faculty of Fisheries, Kagoshima University, Vol. 33, No. 1, p 1-11, December, 1984. 5 Fig, 7 Ref.

Descriptors: *Diffusion coefficients, *Nonconservative material, *Fish farming, *Ushine, *Kagoshima Bay, *Japan, Path of pollutants, Fate of pollutants, Aquaculture, Model studies.

The horizontal eddy diffusion coefficient (DC) is estimated from the distribution of nonconservative material (NM) near a fish-cultivation area taking into account the material discharge, reduction, descending speed of material, and advection by horizontal and vertical water motion. The differential equation about DC is formulated and solved under the following conditions. 1) Consider in the vertical two-dimensional plane of which length is 'L' and the depth 'H'. 2) The distribution of NM is steady and uniform in the longshore direction. 3) The reduction rate, gamma, and the descending speed, W, are uniformly constant. 4) The production, q, has a constant value only in a limited region below the fish cages. The value of q corresponds only to the total NM discharge, T, into the sea by fish cultivation. 5) At z = H, the material dispersion due to vertical diffusion is much smaller than those due to descending and vertical advection. 6) The concentration of NM vertically averaged from z = 0 to H, c, can be represented by c(x) = (C sub o) exp (-alpha squared X x squared). 7) The ratio beta of (C) sub H to c is constant, where (C) sub H is the NM concentration at z = H. 8) The x and z components of mean current velocity, u and (w) sub H can be represented as follows, respectively: u(x) = ((u sub o) X x/L), (w) sub H = ((-u sub o) X H/L). The solution is applied to Ushine area, in the inner part of Kagoshima Bay. The distribution of COD concentration observed in summer of 1977 is used in the estimation of DC. By adopting the parameters to be as follows, H = 20 m, L = 3 km, alpha = 0.000003/cm, C sub o = 5.8 x 10 to the minus 7th power g/cu cm, beta = 0.8, T = 3 ton/day, gamma = 0.01/day, W = 0.3 m/day, and u sub o = 0.5 cm/sec, the value of DC at x = L is calculated to be 161,000 sq cm/sec, of which order of magnitude agrees with that evaluated from the data obtained by the direct measurement of current velocity for a month in summer of 1979 at the 10 m layer of the Ushine area. The total discharge or production, descending speed of material, reduction rate and water motion have the same order of magnitudes of contributions to the evaluated diffusion coefficient. ECOLOGICAL SURVEY OF SEDIMENT FLUX IN COASTAL FISH FARMS - I DECOMPOSITION FEATURES OF THE FLUX (IN JAPANESE),
Kagoshima Univ. (Japan). Faculty of Fisheries.
S. Kadowaki, Y. Inazuka, and H. Hirata.
Memoirs of the Faculty of Fisheries, Kagoshima University, Vol. 33, No. 1, p 43-49, December, 1984. 4 Fig, 2 Tab, 14 Ref.

Descriptors: *Sediment flux, *Fish farms, *Aquaculture, Decomposition, Nutrients, Organic carbon, Nitrogen, Phosphates.

In order to know the decomposition mechanisms of sedimented matter in a coastal fish farm, chemical features of the sediments were observed in comparison with non-fish farm areas. The observations were conducted in December 1980 and August 1981 in the vicinity of the Fisheries Research Laboratory, Kagoshima University. Two-liter-traps were submerged at 1 m, 5 m and 10 m from the sea bottom. The periods of suspension were set to be 1 day, 2 days, 4 days, 7 days and 10 days. Organic carbon, organic nitrogen and total phosphate were analyzed in each observation. Typical examples of the sediment decomposition were observed in 1-day-suspensions of the traps. In August, average organic carbon in fish farm and non-fish farm samples were 15.6 and 5.6 g/sq m/day, respectively. Organic nitrogen concentrations in August were 1.7 g/sq m/day in fish farm and 0.7 g/sq m/day in non-fish farm. Total phosphate, 1.9 g/sq m/day, in fish farm was nineteen times higher that that in non-fish farm. The results obtained in December showed almost the same trends as mentioned above. The decomposition coefficient of organic flux in deep layer, however, was 30-70% higher than that in case of August. (Author's abstract)

SEASONAL CHANGES IN THE DISTRIBUTION OF HETEROTROPHIC BACTERIA IN KAGOSHIMA BAY,
Kagoshima Univ. (Japan). Faculty of Fisheries.
T. Hidaka.
Memoirs of the Faculty of Fisheries, Kagoshima University, Vol. 33, No. 1, p 85-96, December, 1984. 2 Fig, 3 Tab, 18 Ref.

Descriptors: *Kagoshima Bay, *Japan, *Seasonal distribution, *Heterotrophic bacteria, Bacteria, Seawater, Water pollution, Public health.

Seawater samples were collected from 1m, 25m, 50m, and 100m depth layers at 8 stations along the center line of Kagoshima Bay 17 times in selected seasonal intervals during 1977 to 1984. The heterotrophic bacterial cells in the samples were estimated with the plate count method by surface spreading. The microbial cell counts were most abundant at the inner area of the bay in a horizontal distribution, and were most at the 1m deep layer in vertical distribution. They were more abundant in spring and summer than autumn and winter on a seasonal change basis. The range of bacterial numbers in the seawater samples was 10-1,000 cfu/ml. These results mean that the seawater at the sampling stations of Kagoshima Bay has not been polluted very much as yet. (Author's abstract)

SEASONAL CHANGES IN THE GENERIC COMPOSITION OF HETEROTROPHIC BACTERIA IN SEAWATER OF KAGOSHIMA BAY (IN JAPANESE),
Kagoshima Univ. (Japan). Faculty of Fisheries.
T. Hidaka, and S. Shimazu.
Memoirs of the Faculty of Fisheries, Kagoshima University, Vol. 33, No. 1, p 97-105, December, 1984. 67 Fig, 10 Ref.

Descriptors: *Seasonal variation, *Heterotrophic bacteria, *Kagoshima Bay, *Japan, *Bacteria, *Seawater, Fate of pollutants, Pseudomonas, Vibrio, Moraxella, Species composition.

The heterotrophic bacterial flora was sampled in seawater samples collected from the stations of Kagoshima Bay, during 1981 to 1983. The dominant genera in the seawater were Pseudomonas and Vibrio, almost similar to that of open sea water. In the generic compositions, Pseudomonas was the highest in seawater of the inner area of the bay and decreased approaching the entrance; in contrast, the ratio of Vibrio increased. This was confused sometimes, after rainy days, at the stations (St. 3 and 4) near Kagoshima city. In this

case, Moraxella significantly became the most dominant genus, indicating the slight pollution of seawater of this area during a few days. However, the seawater along the center line of Kagoshima Bay was generally not polluted. (Author's abstract)

CONSIDERATIONS ON WATER, OIL AND AIR IN POROUS MEDIA,
Electrowatt Engineering Services Ltd., Zurich (Switzerland).
H. O. Schiegg.
Water Science and Technology, Vol. 17, No. 4/5, p 467-476, 1985. 7 Fig, 3 Ref.

Descriptors: *Groundwater pollution, *Porous media, *Oil pollution, Path of pollutants, Observation wells, Aquifers, Capillary height.

Oil spilled above a phreatic aquifer initially percolates primarily vertically until it reaches the capillary fringe. Subsequently, the oil migrates within the capillary fringe parallel to the groundwater table thereby creating an oil-polluted layer parallel to the groundwater table. The mean thickness of such an oil-polluted layer is denoted by H. The average thickness, H, of an oil-polluted layer parallel to the groundwater table is not equal to the thickness of oil in an observation well. H can be described as a function of the mean capillary height for water in air and of the oil potential or the thickness of oil in an observation well. The necessary thickness of oil on water for oil to enter a porous medium equals twice the mean capillary height of the water saturation curve which is encountered by the propagating oil. (Moore-IVI)

FACTORS CONTROLLING THE SURVIVAL OF VIRUSES IN GROUNDWATER,
Arizona Univ., Tucson. Dept. of Microbiology.
M. V. Yates, and C. P. Gerba.
Water Science and Technology, Vol. 17, No. 4/5, p 681-687, 1985. 4 Fig, 4 Tab, 9 Ref.

Descriptors: *Viruses, *Groundwater pollution, Bacteriophage, Temperature effects, Hardness, Hydrogen ion concentration, Nitrates, Ammonia, Turbidity, Dissolved solids, Calcium, Magnesium.

Viral contamination of groundwater is controlled by two major factors: migration and survival. This study used the coliphage MS-2, which is similar in size and structure to many enteric animal viruses, to identify factors which could be used to predict virus survival in groundwater. Groundwater samples collected from throughout the United States were inoculated with the coliphage MS-2 and the rate of virus inactivation determined. All samples were incubated at the temperature of the native groundwater. All samples were analyzed for pH, nitrates, ammonia, turbidity, total dissolved solids, and calcium, magnesium and total hardness. Multiple regression analysis of the chemical variates indicated that temperature and calcium hardness were significantly correlated with the rate of virus die-off. Temperature alone account for 60% of the variation in decay rate. Using all variates, 94% of the variation could be predicted. The presence or absence of microorganisms had an inconsistent effect on the survival of MS-2. (Moore-IVI)

SORPTION OF AMMONIA NITROGEN ON RIVER BORNE SUSPENDED SOLIDS,
Purdue Univ., Lafayette, IN. Environmental Engineering Lab.
R. F. Wukasch, and L. P. Moos.
Water Science and Technology, Vol. 17, No. 4/5, p 713-718, 1985. 2 Fig, 5 Tab, 3 Ref.

Descriptors: *Fate of pollutants, *Ammonia, *Sorption, *Suspended solids, Wabash River, Indiana, Desorption, Rivers.

Many of the rivers in the midwestern U.S. carry a fairly high level of suspended solids. The ammonia nitrogen carrying capacity of suspended solids collected from the Wabash River (Indiana) was evaluated. Ammonia nitrogen was found to be both sorbable and desorbable from Wabash River suspended solids collected both in summer and in winter. The sorption of ammonia onto river solids was found to follow a Langmuir model and to be reversible. At background river ammonia concentrations of below about 0.2 mg/l, sorbed ammonia carried by the suspended solids is quite low, less than 0.2 mg NH3-N per gm suspended solids. Near outfalls under the right conditions, as much as 15 to 20% of the ammonia discharged may be initially sorbed from solution to be later released downstream when the soluble ammonia concentration decreases. Descriptors: *Phenols, *Cyanide, *Ammonia, *Oil, *Grease, *Stream pollution, *Mathematical models, Fate of pollutants, Decomposition, Multiple regression analysis, Hydraulic transport, Mass balance, Water quality.

Due to complexities in water uses in modern time, water quality management often needs much information in addition to the traditional DO and BOD data, to impose any kind of control on the industrial and municipal discharges into natural streams. The simplistic Monod type of substrate limiting kinetics are not sufficient to express the fate of complex chemicals such as phenol, cyanide, ammonia, oil and grease. This paper presents the kinetics of physical and biological degradation and transformation of such chemicals in natural waters. The kinetics were developed through multiple regression analysis using data monitored over a year from a river in Pennsylvania, USA. The conventional unidirectional hydraulic transport and mass balance equations were then combined with these kinetics to predict the steady state water qualities in various reaches of the river under a specific set of known external discharges. When compared to the monitored water quality data under that specific set of external discharges, the predictions were found to be satisfactory. Some disagreement was observed in cyanide concentrations in the most downstream section of the 25 mile stretch of river. (Author's abstract)

From 1980 to 1982, two investigations of the chronic pollution of roadway runoff water were carried out in areas having different pluviometric characteristics. The runoff from two hundred pluviometric events was characterized using highly rigorous methodologies, with a view to estimating the annual pollution load. The annual loads were determined; they show that the (French) official instructions hither-to followed were rather pessimistic. On the other hand, greater vigilance is required as regards the loads that may be contributed by an isolated event, but it is not possible to characterize the parameters that will give rise to such an event. A few rain events can introduce into the environment, in short time, as much as 30% of the annual pollution load of motorway runoff waters. (Author's abstract)

METAL MOBILIZATION IN HOME WELL WATER SYSTEMS IN NOVA SCOTIA,
Dalhousie Univ., Halifax (Nova Scotia). Inst. for Resource and Environmental Studies.
O. Maessen, B. Freedman, and R. McCurdy.
Journal of the American Water Works Association, Vol. 77, No. 6, p 73-80, June, 1985. 2 Fig, 4 Tab, 41 Ref.

Descriptors: *Well water, *Nova Scotia, *Metals, *Plumbing, Pipes, Metal mobilization, Water quality, Drinking water, Copper, Zinc, Lead, Cadmium, Heavy metals, Leaching.

A study of private wells in rural Nova Scotia found that concentrations of metals such as cadmium, zinc, copper, and lead increased in water that remained in the distribution system overnight. Metal mobilization of copper, lead, and zinc occurred in significant amounts from the plumbing systems of the homes sampled. In many cases this leaching caused concentrations of copper and lead to be in excess of the recommended Canadian drinking water limits within only a few hours of standing in the water pipes. Water samples containing copper and lead concentrations in excess of the recommended limits were obtained from a large proportion of the homes sampled in each of the four communities studied. The amount of metal mobilization varied greatly from house to house but, on average, the absolute amount of metal mobilization did not differ among the homes in the four communities. Correlation analyses helped to confirm that indexes commonly used to assess the corrosive tendency of a water were not good predictors of the degree of metal leaching that could occur in a given water. Stepwise multiple regression analyses helped to identify 12 water chemistry variables as being related to the degree of metal mobilization observed. These were potassium, sodium, calcium, magnesium, and manganese; the chloride, nitrate, hydrogen and sulfate ions; and dissolved oxygen, and conductivity. No obvious generalized relationship was found between the pH of the water and the degree of metal leaching. Because of the high concentrations of copper and lead found in samples of standing water it is recommended that residents in homes with metal piping allow the water in the pipes to flush for several minutes before use in the morning or if the water has not been used for several hours. NITROGEN TRANSFORMATIONS IN THE BALTIC PROPER: DENITRIFICATION COUNTERACTS EUTROPHICATION,
Goeteborg Univ. (Sweden). Dept. of Microbiology.
U. Ronner.
Ambio, Vol. 14, No. 3, p 134-138, 1985. 4 Fig, 2 Tab, 39 Ref.

Descriptors: *Baltic Sea, *Nitrogen, *Eutrophication, *Denitrification, Water pollution, Nitrogen removal, Marine environment, Fate of pollutants, Bacteria, Phytoplankton.

Nitrogen plays an important role in marine eutrophication and its increased addition to the Baltic Sea by human activities could upset the ecosystem if its loss from the system is also not substantial. The major process of nitrogen loss is denitrification, a bacterial process that converts nitrate to nitrogen gas during anoxic or near-anoxic conditions. A budget is presented which is based on rate measurements for many processes and gives improved estimates for denitrification. A general diagram of the nitrogen flow in the Baltic ecosystem is pictured. Inputs to the Baltic proper include atmospheric deposition, river runoff, diffusive and advective transport - external, and nitrogen fixation. Nitrogen transformations within the Baltic proper include phytoplankton biomass and assimilation, microbial biomass and mineralization, nitrification, and diffuse and advective transport - internal. Outputs from the Baltic proper include nitrogen gas, immobilization, transport by surface currents, and emission of nitrous oxide to the atmosphere. The controlling factors for denitrification below the halocline of the Baltic are clearly oxygen and nitrate, while denitrification above the halocline probably is stimulated by increasing amounts of nitrate from land. In the Baltic proper today, organic nitrogen seems so far to be efficiently transformed, via ammonium and nitrate, to nitrogen gas. Thus denitrification seems to be preventing excessive eutrophication by removing nitrogen, the limiting nutrient for primary production. The reported budget illustrates the potential importance of denitrification in controlling eutrophication in the Baltic, and emphasizes the necessity for further studies in this area. (Baker-IVI)

INDICATIONS OF THE CAPACITY FOR RAPID REVERSIBILITY OF LAKE ACIDIFICATION,
Uppsala Univ. (Sweden). Limnologiska Institutionen.
C. Forsberg, G. Morling, and R. G. Wetzel.
Ambio, Vol. 14, No. 3, p 164-166, 1985. 3 Fig, 3 Tab, 15 Ref.

Descriptors: *Acid lakes, *Acidification, *Acid rain, *Sulfates, *Sweden, *Water pollution effects, Water pollution sources, Hydrogen ion concentration, Nitrous oxides, Lakes.

Acidification in a number of lakes in western Sweden reached a maximum during the middle of the 1970s, with sulfate concentrations of 270 to 290 micro-eq/l and pH values of 4.4 to 4.5. In 1977 this trend reversed, and decreases in the concentrations of sulfate and hydrogen ions were observed. The main reason for this partial improvement, 0.3 to 0.4 pH units at most, was a decrease in wet deposition of sulfate; the observed decrease was about 20 percent at the meteorological sampling location Bohus Malmon, in western Sweden. In contrast to the wet deposition of sulfate, the wet deposition of hydrogen ions increased, probably as a result of increased emissions of nitrous oxides. A sulfate reduction of 40-100 micro-eq/l was found for several lakes. There was a correlation between sulfate and H(+) during both the acidification and deacidification phases. Of special interest is the hysteresis that occurs between these phases. When sulfate concentrations had decreased to previous levels, H(+) values were higher than during the acidification phase. Increased precipitation, which was also more acid, counteracted the improvements obtained by reduced sulfate concentration. It was concluded that sensitive lakes appear able to begin recovery quickly when sulfate concentration are reduced. (Author's abstract)

MULTIVARIATE ANALYSIS OF WATER CONTAMINATION BY HEAVY METALS AT DONANA NATIONAL PARK,
Consejo Superior de Investigaciones Cientificas, Madrid (Spain). Inst. de Quimica Organica General.
J. Gonzalez, L. M. Hernandez, A. Hernan, and G. Baluga.
Bulletin of Environmental Contamination and Toxicology, Vol. 35, p. 266-271, August, 1985. 3 Fig, 2 Tab, 9 Ref.

Descriptors: *Heavy metals, *Donana National Park, *Water pollution sources, *Mines, Multivariate analysis, Mathematical studies, Cadmium, Mercury, Lead, Copper, Zinc.

Donana National Park (Spain) is a natural park about 60,000 Ha in size. It is a very important stopping ground and winter habitat for migratory birds that breed in northern Europe. One of the most important water supplies for the survival of the park is the Guadiamar River. The Agrio river is a tributary of the Guadiamr, and it flows across an important mining field which is currently in operation. The watershed was sampled to determine whether there was any possible contamination from the mining. Sampling points were located in the mining area, the marshes, and the stabilized sands. Cd, Pb, Cu and Zn pollution were found in the waters of the study area. Contamination was highest in the mining area, high in the northern side of the marshes, moderate in southern site of the marshes, and low in the stabilized sands. This conclusion is linked with the fact that the hydraulic system of the stabilized sands is independent from that of the marshes. The stabilized sands only depend on the rain and the subterranean waters. High Hg pollution was found throughout the area studied. (Baker-IVI)

BROMINATED PHENOLS AND ANISOLES IN RIVER AND MARINE SEDIMENTS IN JAPAN,
Osaka Prefecture Inst. of Public Health (Japan).
I. Watanabe, T. Kashimoto, and R. Tatsukawa.
Bulletin of Environmental Contamination and Toxicology, Vol. 35, p 272-278, August, 1985. 3 Fig, 1 Tab, 13 Ref.

Descriptors: *Phenols, *Anisoles, *Sediments, *Japan, Fate of pollutants, Organic compounds, Marine sediments, River sediments, Halogenated hydrocarbons, Tribromophenol, Tribromoanisole.

The environmental levels of brominated phenols have been determined along with chlorinated phenols in river and marine sediments collected from Osaka, Japan. The brominated and chlorinated anisole levels in the samples were also examined. At site no. 7 brominated phenols, were found in the samples along with chlorinated phenols. No dibromophenol was found. Also present in the sediment samples was 2,4,6-tribromoanisole along with chlorinated anisoles. The residue levels of halogenated phenols and anisoles in the sediment samples are given as determined on a dry weight basis. The brominated phenol levels were lower than those of the chlorinated phenols being about one-tenth the chlorinated phenols content. Tribromophenol was found in nearly all the samples analyzed and was thus considered an ubiquitous environmental contaminant, though its residue level is generally low. However, higher residue levels of this compound were found in the two sediment samples collected at sites 7 and 8, and were nearly the same as those of the organochlorinated pesticides. 2,4,6-Tribromoanisole was found in only two of the 12 samples analyzed and had a very low residue level. Other brominated anisoles were absent from the samples. Brominated phenol residue levels in sediment samples collected at sampling sites 7 and 8 were considerably higher than those collected at other sites. Sewage treatment plants were located in the vicinity of sampling sites 7 and 8. (Baker-IVI)

CALIBRATION OF A MASS TRANSPORT MODEL USING ENVIRONMENTAL TRITIUM,
Vrije Univ., Amsterdam (Netherlands). Inst. voor Aardwetenschappen.
J. C. Herweijer, G. A. Van Luijn, and C. A. J. Appelo.
Journal of Hydrology, Vol. 78, No. 1/2, p 1-17, May, 1985. 10 Fig, 14 Ref.

Descriptors: *Mass transport models, *Model studies, *Tritium, *Aquifers, Isotope studies, Path of pollutants, Groundwater contamination, Animal wastes.

Tritium profiles of groundwater were obtained by detailed vertical sampling of a 20-m thick aquifer comprising fluvioglacial sediments in the central part of The Netherlands. Using the known environmental tritium input time series since 1951, these profiles were used to calibrate the Random Walk model of T.A. Prickett et al. To perform this procedure the model was modified to allow vertical use and a time-dependent non-instantaneous input of a decaying radioactive tracer. During this calibration the following parameters were varied: (1) geological geometry (position and extent of a clay lens); (2) permeability variations; (3) ratio of net precipitation and effective porosity; and (4) longitudinal and transverse dispersivity. The calibrated model was hence used to predict the flushing of manure contamination from the aquifer. The applied calibration technique has proved useful to test and roughly calibrate the hydraulic properties estimated from the logs of a limited number of borings, with the accuracy needed for mass-transport modelling. Compared with the very detailed drilling program that is usually required to obtain such detailed information, this tritium-based calibration seems competitive for shallow phreatic aquifers. (Author's abstract)

SALT-WATER-FRESHWATER TRANSIENT UPCONING - AN IMPLICIT BOUNDARY-ELEMENT SOLUTION,
Kansas State Geological Survey, Lawrence.
M. Kemblowski.
Journal of Hydrology, Vol. 78, No. 1/2, p 35-47, May, 1985. 10 Fig, 13 Ref. U.S. Department of Interior, Bureau of Reclamation grant 4-FG-93-00080.

Descriptors: *Saline water intrusion, *Saline-freshwater interfaces, *Upconing, *Implicit solutions, *Boundary element solutions, Boundary conditions, Aquifers, Groundwater contamination, Model studies.

The most difficult part of the modeling of salt-water intrusion is the simulation of the motion of the transition zone between fresh and salt water. If the width of the transition zone is relatively small compared to the aquifer thickness, the sharp-interface approximation may be introduced. The boundary-element method was used to solve the set of partial differential equations describing the flow of salt water and fresh water separated by a sharp interface in the vertical plane. In order to improve the accuracy and stability of the numerical solution, a new implicit scheme was developed for calculating the motion of the interface. The solution does not use the Dupuit approximation, thus providing a better model for the cases in which the vertical component of the flow is significant. For the simulation of the interface motion, a special implicit scheme was developed, which gives substantially better results than the explicit solution. The performance of this scheme was tested by means of numerical simulation. The numerical results were compared to experimental results for a salt-water upconing under a drain problem. The numerical model may be used to analyze steady and unsteady, stable and unstable, salt-water upconing problems. (Collier-IVI)

KTON DYNAMICS IN A HYPER-ACKISH-WATER BAY,
(Finland). Dept. of Limnology.

nternationale Vereinigung Limnolo-No. 4, p 2203-2207, 1985. 3 Tab, 20

*Phytoplankton, *Brackish water, es composition, *Kaupunginselka den, *Poorvoo, *Finland. *Physico-aracteristics, Cyanophyta, Algal ss, Phytoplankton, Water tempera-nce, Nutrients, Water pollution ef-ency.

onships among phytoplankton com-sition, phytoplankton biomass, pri-vity in vitro, water temperature, linity), freshwater influx, and nutri-

ent levels were examined in Kaupunginselka Bay (Stadsfjarden) at Poorvoo, Finland. The bay is a shallow, sewage-polluted, brackish embayment at the mouth of the River Porvoonjoki (Borga River), in which the growth of Oscillatoria agardhii has been a problem. Linear correlation coefficients were calculated among various phytoplankton and physicochemical parameters. For blue-green algae, nutrients and salinity were the main factors influencing biomass variations, whereas for green algae and diatoms, water temperature and salinity, respectively, appeared to be key factors. The factors influencing primary productivity reflected the Cyanophycean dominance of the phytoplankton. Freshwater discharge into the bay influenced phytoplankton through its effect on the rate of water renewal. A very significant correlation was seen between phytoplankton biomass and residence time of water in the bay (r=0.726**). The Cyanophycean dominance in the bay was partly due to low light environment; the Secchi disk transparency of 0.10-0.25 indicated a light environment favorable to 'shadow plants' like O. agardhii. Low correlation coefficients were exhibited by numerous environmental factors, which makes it impossible to select a key factor regulating phytoplankton succession in this area. (Rochester-IVI)

PATTERN RECOGNITION TECHNIQUES TO DETERMINE BENTHIC INVERTEBRATE TROPHIC AND COMMUNITY RESPONSES TO INDUSTRIAL INPUT,
Beak Consultants Ltd., Calgary (Alberta).
R. A. Crowther, and M. E. Luoma.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2226-2231, 1985. 2 Fig, 1 Tab, 8 Ref.

Descriptors: *Thunder Bay, *Ontario, *Ecological impact, *Water pollution effects, *Benthos, *Pulp and paper industry, Industrial wastewater, Species composition, Statistical analysis, Species distribution, Phenols, Oligochaetes, Midges, Mollusks.

The pattern recognition techniques of reciprocal averaging ordination (RAO) and discriminant analysis (DA) successfully defined the extent of, and placed boundaries between, areas of chronic and acute pollution associated with pulp and paper mill effluent in Lake Superior. Sediments of the near-shore environment of Thunder Bay, Ontario, Canada were sampled with an Ekman grab with the intention of assessing the appropriateness of a proposed limited use zone (LUZ), which had originally been established solely on the basis of phenolics concentration. The benthic fauna generally was dominated by Oligochaeta, Chironomidae, and Mollusca. Five sequences of benthic fauna were identified by RAO and DA; the sequences appeared to represent a trophic gradient from mesotrophy through eutrophy to chronic pollution. The principal causative agents for the observed faunal patterns were concentration gradients in dissolved solids, phenolics, wood fiber, and dissolved oxygen content. In comparison with the LUZ originally proposed, the area of actual system perturbation as shown by the benthos was much larger, although the area of chronic pollution effects was small. The proposed LUZ consisted of a roughly rectangular area extending 700 m offshore and about 1,200 m wide. The zone of influence according to benthos analysis indicated an irregularly-shaped zone of influence extending 1,300 m offshore with a width of 2,800 m. Numerical indices alone probably would not have yielded the results obtained in this study; ecological information and the pattern expressed by the fauna should be incorporated in studies of system perturbations. ASBESTOS FIBERS IN LAKES AND STREAMS,
Vermont Univ., Burlington. Dept. of Zoology.
E. B. Henson.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2232-2237, 1985. 3 Fig, 16 Ref.

Descriptors: *Asbestos, *Water pollution effects, Chrysotile, Daphnia, Paramecia, Water analysis, Physical analysis, Microscopic analysis.

Chrysotile is the most common species of asbestos; literature on asbestos is voluminous, but little has been reported on the effects of this mineral on plants and animals in aquatic ecosystems. Several methods have been used for measuring the asbestos fiber content of water, including colorometric tests, light microscopy, polarized light microscopy, dispersion staining, x-ray diffraction, proton-induced x-ray emission, transmission electron microscopy, scanning electron microscopy, and selected area electron diffraction. Laboratory procedures for asbestos present problems because water acidity, high alkalinity, and methods of handling affect the size, and hence number, of fibers in a water sample. Concentrations of asbestos reported in natural waters range from undetectable (non-contaminated parts of Lake Champlain (USA)) to 1.200 x 10 to the 9th power/liter in water draining mines from the city of Asbestos, Quebec. In laboratory experiments, survivorship of Daphnia pulex was negatively correlated with concentration of chrysotile fibers over the range of approx 20-550 mg/l. Autopsies of the animals that died showed a clumping of fibers and congestion around the antennal setae and legs, which may have restricted swimming, and there was some evidence that the animals were impaled during feeding. Similar experiments with Paramecium in culture at various concentrations of asbestos fibers revealed no difference between controls and experimental cultures in terms of growth rate or asymptotes. DIATOM COMMUNITIES OF THE POLLUTED RIVERS OF CENTRAL POLAND (LES COMMUNAUTES DES DIATOMEES DANS LES RIVIERES POLLUEES DE LA POLOGNE CENTRALE),
Lodz Univ. (Poland). Inst. of Environmental Biology.
B. Rakowska.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2319-2322, March, 1985. 2 Fig, 1 Tab, 3 Ref.

Descriptors: *Diatoms, *Water pollution effects, *Rivers, *Poland, Headwaters, Downstream, Ecological distribution, Industrial wastewater, Food processing industry, Bioindicators, Wastewater pollution.

Qualitative and quantitative analysis of the diatoms found in polluted rivers in Central Poland reveals that a small number of species are characteristic of the headwaters, and the number of species increases downstream. The rivers are polluted in the upper sectors. The influence of pollution on the diatom communities is evident in the river Bzura where the number of taxons are reduced two-fold and the number of individuals is reduced 100-fold. Downstream, the number of taxons and individuals increases with the improvement in physical and chemical conditions. In the rivers Rawka and Mroga, there is a simultaneous reduction in the number of taxons and the density of diatoms downstream of the point of introduction of effluents from the food processing industry. Analysis of the diatoms communities led to the establishment of a list of typical species for waters of different degrees and types of pollution; species are listed which have a great tolerance for physicochemical gradients. INFLUENCE OF ORGANIC POLLUTION ON THE MACROINVERTEBRATE COMMUNITIES OF MOUNTAIN STREAMS,
Innsbruck Univ. (Austria). Inst. fuer Zoologie.
M. Margreiter-Kownacka.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2324-2326, 1985. 1 Fig, 9 Ref.

Descriptors: *Organic matter, *Water pollution effects, *Mountain streams, *Macroinvertebrates, *Poland, *Sucha Woda, *Roztoka, *Rybi Potok, *Gurgler Ache, *Austria, Ecological effects, Phys-

icochemical characteristics, Benthos, Alpine regions.

Faunal composition in relation to pollution level was compared in the Tatra (Poland) streams Sucha Woda, Roztoka and Rybi Potok, and the alpine stream Gurgler Ache (Austria). The method employed included a detailed description of the stream or river and its basin, selection of research localities, a detailed description of the locality and its physico-chemical conditions, and standardization of sampling technique throughout. The dominant groups of macrofauna in the upper courses are Chironomidae (mainly Orthocladiinae in the Tatra springs and streams and Diamesinae in the alpine glacier-streams) and Ephemeroptera (mainly Baetis alpinus). Plecoptera constitute an av 5%. In the lower courses of the alpine streams Trichoptera play an important role. Under the influence of pollution the structure of the community changes. The influence occurs seasonally in Gurgler Ache where tourists are present mainly in winter. At a station on this stream where tourist influence was present, Ephemeroptera were a smaller part of the percentage composition and Chironomidae and Oligochaeta were a much larger part, than at another, unpolluted station. Plecoptera were also much less abundant at the polluted station, particularly in winter. (Rochester-IVI)

INFLUENCE OF THE SEWAGE TREATMENT PLANT EFFLUENTS ON THE STRUCTURE OF THE BENTHIC COMMUNITIES OF LAKE OF GENEVA,
Geneva Univ. (Switzerland). Unite de Biologie Aquatique.
B. Crozet.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2327-2331, 1985. 2 Fig, 16 Ref.

Descriptors: *Benthos, *Lake Geneva, *Switzerland, *Wastewater pollution, *Water pollution effects, Stones, Nutrients, Dreissena, Gammarus, Midges, Trichoptera, Caenis, Tanytarsids, Tubificids, Pisidium, Orthocladiinae, Dugesia, Pentaneurini, Lynaea, Spaerium, Naididae, Asellus, Valvata, Procladius, Psychodidae, Turbidity, Ammonia, Nitrates, Phosphorus.

The influence of the effluent from two small sewage treatment plants (STPs) (3,000 population equivalents) on the stony littoral zone fauna of Lake Geneva was apparent in faunas collected by gathering stones from the bottom. The diversified community of the unaffected area was characterized by Dreissena polymorpha, Gammarus sp., and Chironomids. Numerous other taxa were present. Under the influence of STP outflows, D. polymorpha, Gammarus sp, Hirudinea (2 spp), Trichoptera larvae (6 spp), Caenis horaria, and Tanytarsids exhibited declines; turbidity, NH4, NO3, total P, and total insoluble matter increased around STP outfalls. Groups exhibiting increases in numbers at STP outfalls were Tubificids, Pisidium sp, Orthocladiinae, Chironomids, Dugesia sp, Pentaneurini sp, Lymnaea auricularia, and Sphaerium corneum. Naididae and Asellus aquaticus populations tended to remain unchanged. New members of the fauna near the STPs were Valvata piscinalis, Procladius choreus, and Psychodidae larvae. The effluents cause two main modifications that affect the benthic community: (1) the substratum becomes more homogeneous as insoluble organic matter partially or totally covers the stones, and (2) the wastewater effluents modify the available food by eliminating the epilithic algae, resulting in declines in herbivorous organisms and adaptation by omnivorous invertebrates (L. auricularia, A. aquaticus). MULTILEVEL APPROACH TO THE ASSESSMENT OF ECOTOXICOLOGICAL EFFECTS IN A HEAVY METAL POLLUTED STREAM,
National Research Council of Canada, Ottawa (Ontario). Div. of Biological Sciences.
P. J. Sheehan, and A. W. Knight.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2364-2370, 1985. 3 Fig, 3 Tab, 14 Ref.

Descriptors: *Toxicity, *Heavy metals, *Water pollution effects, *Copper, *Zinc, *Little Grizzly Creek, *Plumas County, *California, Fish, Trout, Stoneflies, Mayflies, Caddisflies.

Copper and zinc pollution emanating from an abandoned mine appears to account for the absence of fish and many invertebrates in Little Grizzly Creek, Plumas County, California. No fish were found (by electroshock) in pools at contaminated sites, but populations of rainbow trout and brook trout were abundant in pools above the polluted zone. Stonefly and mayfly nymphs were absent or rare, generally less than 5% of total individuals, and caddisflies made up less than 10% of pooled annual samples, from contaminated sites. The most striking feature of the polluted zone was the overwhelming numerical predominance of chironomid collector-gatherers in invertebrate collections and the rarity of large predatory or omnivorous species. In situ toxicity bioassays showed that summer concentrations of copper at the least contaminated of the affected sites (20-320 micro-g/l Cu) overlap LC50 values for rainbow trout fry within an acute exposure period (about 5-100 hr), a finding which seems to account for the failure of trout to survive in the stream. Stonefly (Doroneuria) nymphs were less sensitive to the mine effluent: 36% mortality was observed in 96 hr at the most contaminated site (1,700 micro-g/l Cu). Evidently other factors than acute toxicity, such as long-term effects or low prey density, account for the absence of Doroneuria in Little Grizzly Creek. Although chironomids dominated numerically at the contaminated sites, fewer genera were present there than in the reference samples. Furthermore, there was a relative absence of < 2 mm size-class individuals, suggesting serious impairment of recruitment at least two of the polluted sites. This effect was confined mainly to the fall season at the third polluted sampling site. (Rochester-IVI)

CHARACTERISTIC DISTRIBUTION OF CHIRONOMIDS IN THE RIVERS POLLUTED WITH HEAVY METALS,
National Inst. for Environmental Studies, Tsukuba (Japan).
M. Yasuno, S. Hatakeyama, and Y. Sugaya.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2371-2377, 1985. 3 Tab, 16 Ref.

Descriptors: *Midges, *Heavy metals, *Bioaccumulation, *Water pollution effects, *Japan, *Yoshino, *Mazawa, *Senasaka, Metals, Cadmium, Copper, Lead, Zinc, Ecological effects, Species composition, Animal tissues.

Chironomids collected in three second-order streams, tributaries of the River Mogami, Yamagata Prefecture, Japan, included three taxa that may be tolerant of heavy metal pollution. The three streams, Yoshino, Mazawa, and Senasaka, receive effluent containing Cd, Cu, Pb, and Zn from abandoned copper mines. A total of 60 species of chironomids were recovered from the three streams. Orthocladiinae had the greatest number of species (35); Chironominae had 15 species. Three species of Orthocladiinae, Eukiefferiella sp A, Orthocladius sp A and Cricotopus sp, were common in all three streams, although the streams are more than 30 km apart. Tolerance of heavy metal pollution appeared to be in the order Eukiefferiella sp A > Orthocladius sp A > Cricotpus sp; none could tolerate the conditions at one station on the River Senasaka, where 1,067 micro-g/l Cu and 2,345 micro-g/l Zn were found in water of pH 4.6. Eukiefferiella sp A, Orthocladius sp A, and Polypedilum sp all accumulated heavy metals in their tissues, although the number of times the river water concentration in their tissues varied by species and by location. For example, Eukiefferie A accumulated Cd 660 times on a dry weight on the other hand, Polypedilum sp, in a pond 2.2, with a copper concentration of 8,498.0 g/l, accumulated far less Cu (24.8 micro-g/ weight) than Eukiefferiella sp A (1,816.0 mic g dry weight) in water of much lower conc tion (48.4 micro-g/l). The three species of C cladiinae were identified as indicators of metal pollution; they may be new specie specific to such environments. The chiron inhabiting the regions polluted with heavy seem to have the ability not to uptake the metals or to excrete them rapidly. (Rochester

DRIFT RESPONSE OF AQUATIC INSECTS TO COPPER,
Geological Survey, Menlo Park, CA.
H. V. Leland.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2413-2419, 1985. 1 Fig, 1 Tab, 16 Ref.

Descriptors: *Aquatic drift, *Aquatic insects, *Copper, *Metals, *Water pollution effects, *Convict Creek, *California, Animal behavior, Mayflies, Caddisflies, Behavior, Species composition.

Different responses to continuous copper dosing were observed among drift insects in a section of the oligotrophic Convict Creek, California. Convict Creek, which has a pH in the range 7.9-8.5, and is always at or near saturation with dissolved oxygen, received copper continuously at rates of either 2.5, 7, 15 micro-g/l (approx 12, 35, and 75 nanogram/l Cu(2+)). Declines in population densities of common Ephemeroptera coincident with initial increases in drift density were evident in stream sections dosed with 7 and 15 micro-g/l total Cu. Population densities of many common aquatic Diptera (Antocha monticola, Hexatoma spp, Simulium spp, and Chironomidae) also declined at these doses, but drift densities of these taxa did not increase appreciably at these concentrations. Adults of the common Coleopterans Optioservus divergens and Cleptelmis addenda showed an increased propensity for drift at 15 micro-g/l total Cu, but neither species declined in the benthos, suggesting that Elmidae respond to sublethal copper concentrations by an increase in activity. Common insect taxa in the benthos and the drift were identified. Many were nocturnal, with the mayfly Baetis spp numerically dominant in the post-dusk drift. The caddisfly Brachycentrus americans was the only common drifting aquatic insect that was clearly more active during the day than at night. Drift densities of most of the common aquatic insects exhibited a consistent diel periodicity even in the presence of added copper. Drift densities were highest during periods when foraging normally occurred. (Rochester-IVI)

Descriptors: *Parathion, *Insecticides, *Water pollution effects, *Macroinvertebrates, Aquatic drift, Species composition, Ecological effects, Toxicity.

Parathion, when added to an experimental stream in a manner simulating an accidental spill, produced rapid catastrophic mortality in stream insects; this impact was reflected in the rate and composition of drift, thus demonstrating that drift collections provide a way to reveal both the direct lethal effect and the successive recolonization and stabilization process of the community. An acute pollution event lasting 6 hr was produced by achieving a concentration of 1 + or - 0.18 mg/l parathion in a reach of stream in which drift in and out of the reach was monitored and substrates above and within the reach were sampled. The choice of concentration and duration was based on initial toxicity experiments which showed LC50s as follows: Brachidanio rerio (Pisces), 5.64 mg/l, Biomphalaria glabrata (Gastropoda), 8.09 mg/l; and Daphnia magna, 0.004 mg/l; and LT50s as follows: Echinogammarus stammeri, 92 min; Hydropsyche pellucidula, 110 min; and Baetis rhodani, 65 min. After the 6 hr dosing of the experimental stream, 100% of the Plecoptera, 78% of the Diptera, and 30% of the Trichoptera and Amphipoda had died on the first series of substrates, which were less than 100 m downsteam from where the parathion was introduced. By 24 hr after parathion release, 100% of the Diptera, 90% of the Amphipoda, 61% of the Trichoptera, 25% of the Isopoda, and 37% of the Coleoptera had died. At the substrates about 200 m below the release point, mortality continued after 24 hr, reaching 100% of the Trichoptera, Amphipoda, and Isopoda and 50% of the Coleoptera after 7 days. No mortality was observed in Mollusca and Oligochaeta species. Recolonization observed 30 days after the experiment resulted in a community of significantly different structure than the one present at the upstream station at the same time, suggesting a continuing, medium-term effect of pesticide release on the recolonization process. To investigate all aspects of an aquatic ecosystem and to follow the fate of added chemicals, as well as the breakdown products, a series of polyethylene-lined ponds were constructed. The linings of these ponds were covered with sediment and Myriophyllum spicatum plants were implanted in this sediment. Each major component of the food web was analyzed and interactions between the components were compiled. Specifically in this report, the chemistry of the 2,4-D and 2,4-DCP as well as the phytoplankton population fluctuations in association with the macrophyte, M. spicatum, for the 1981 tests is presented. The populations of dominant algal species in the treated ponds were corrected by subtracting the appropriate populations found in the control ponds. Species whose populations increased after treatment include Scenedesmus incrassatulus and Oscillatoria limnetica with other species having slight enhancements. Oocyctis eremosphaeria and Cosmarium cf. punctatum exhibited inhibition after treatment but soon recovered. By examining all components of the food web in lined-pond ecosystems, the fate and impact of suspected toxic substances can be determined under natural environmental conditions. (Baker-IVI)

Since 1974, a campaign to interrupt transmission of the parasitic disease onchoceriasis in 7 states in western Africa has included the regular application of biodegradable insecticides to eliminate the aquatic larval phase of the insect vector. The insecticides used were temephos, chlorphoxime and the biological insecticide Bacillus thuringiensis. Surveillance of the fish populations and aquatic invertebrates was carried out for 8 years to determine the effects of the insecticide treatment. The treatment of rivers has not brought about a perturbation in the fish populations. There was an effect on the lotic invertebrates, but it was at acceptable levels with all of the insecticides studied. As long as the fish do not suffer serious effects from the reduction in the numbers of invertebrate food species or the absence of some species, the human health concerns will outweigh the effects on the aquatic fauna. INFLUENCE OF PESTICIDES IN THE POLLUTION OF CONTINENTAL AFRICAN WATERS (INCIDENCE DES PESTICIDES DANS LA POLLUTION DES EAUX CONTINENTALES AFRICAINES),
Office de la Recherche Scientifique et Technique Outre-Mer, La Teste (France).
C. Dejoux.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, Part 4, p 2452-2456, March, 1985. 10 Ref.

Descriptors: *Pesticides, *Africa, *Water pollution effects, Agricultural chemicals, Vector control, Aquatic animals, Invertebrates, Water quality, Fish, Water pollution control.

The efforts to control major epidemic diseases in Africa necessitate the frequent introduction of pesticides into the aquatic environment or their use in the immediate area. The use of pesticides in agriculture is also very great. The effects of pesticides on the fauna of aquatic ecosystems in Africa was reviewed. Long-term, increasing effects including reduction in water quality and massive deaths of invertebrates can result from badly-used pesticides; this in turn can lead to the reduction of fish stocks. The same effect may result from pesticides which are directly toxic to fish. When pesticides are used on a large scale, whether temporal or spatial, strict control is necessary. In spatially broad pesticide programs, a permanent collaboration between users and environmental scientists may be necessary to forsee the impact. Monitoring is essential in such circumstances. MODEL FOR FORECASTING ACUTE TOXICITY OF RIVER WATER FOR FISH (MODELE DE PREVISION DE LA TOXICITE AIGUE DES EAUX DE RIVIERES POUR LE POISSON),
Metz Univ. (France). Faculte des Sciences.
J. C. Pihan, and G. Landragin.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2457-2462, 1985. 11 Fig, 1 Tab, 7 Ref.

Descriptors: *Model studies, *Toxicity, *Fish, *Forecasting, Ammonia, Nitrates, Cyanide, Phenols, Heavy metals, Detergents, Potassium, Sodium.

A 'concentration and addition type' model uses the CL50-48h proportions addition method, in order to assess a global index of toxicity. This model takes into account the following parameters: NH4, NO2, CN, phenols, Zn, Cu, Pb, Cd, Ni, K, Na, anionic detergents, As, Se, Cr, Mn, calculated in water. It calculates the CL50-48h of these toxicants according to environmental parameters in each sample. A statistical and graphic interpretation of the results enables one to give a qualitative and quantitative judgment of the toxicity level of a river, and the safety measures to observe. This model also allows one to test a future scenario for the river. (Author's abstract)

ACCUMULATION OF RADIUM-226 BY POPULATIONS OF THE FRESHWATER MUSSEL, VELESUNIO ANGASI, FROM THE ALLIGATOR RIVERS URANIUM PROVINCE, NORTHERN TERRITORY, AUSTRALIA,
Australian Atomic Energy Commission Research Establishment, Sutherland.
R. A. Jeffree.
Verhandlung Internationale Vereinigung Limnologie, Vol. 2, No. 4, p 2486-2492, March, 1985. 3 Fig, 2 Tab, 10 Ref.

Descriptors: *Radium radioisotopes, *Mussels, *Alligator Rivers Uranium Province, *Northern Territory, Australia, Billabongs, Calcium, Magnesium, Uranium mines.

The radionuclide Ra-226 naturally leaches from uranium deposits in the Alligator Rivers Uranium Province, Northern Territory. Mussels sampled from Corndorl, Georgetown and Mudginberri Billabongs individually vary over an order of magnitude in their Ra-226 tissue concentration. Because of this variability, large actual increases in the tissue concentration of Ra-226 above these levels would have to occur before a statistically significant increase could be demonstrated. The predictive relationships established between Ra-226 concentration and size measurements, and Ca and Mg concentration can be used to reduce this variance. For each billabong, these regression equations can be used to account for between 83 and 97% of the variance in Ra-226 concentration. For mussels from the three billabongs, the significant predictors of Ra-226 concentration show similar relationships. The concentration of Mg, in combination with size measurements, is a significant predictor of Ra-226 in mussels from Georgetown and Mudginberri billabongs. Because predictive relationships can be population specific, they would need to be separately determined for each billabong from which mussels were harvested for human consumption, and which could potentially receive uranium mine effluent or were to be used as a control sampling site. The pattern of accumulation of Ra-226 indicates that V. angasi does not regulate its concentration of Ra-226, but continues to accumulate Ra-226, and also Ca, as it increases in size. The accumulated Ra-226 is located predominantly together with Ca and Mg in granular deposits that are dispersed throughout the tissues, and that increase in abundance with increasing mussel size. EFFECTS OF POWER PLANT ENTRAINMENT ON PHYTOPLANKTON RESPONSE,
Michigan Univ., Ann Arbor. Great Lakes Research Div.
W. Y. B. Chang, and R. Rossmann.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2493-2497, March, 1985. 2 Fig, 1 Tab, 5 Ref.

Descriptors: *Phytoplankton, *Powerplants, *Entrainment, *Thermal pollution, Water pollution effects, Chlorophyll, Phaeophytin, Primary productivity, Cooling water, Heated water, Corrosion.

The effect of entrainment on phytoplankton has been investigated using chlorophyll and cell counting techniques alone from 1975 to 1979 and in conjunction with C-14 uptake methods since 1979. Chlorophyll and phaeophytin concentrations as well as cell counts do not significantly change in water which has passed through the co
cooling system; productivity is reduced sig
ly (20-80%). Between 1980 and 1982, the r
ship of this reduction to temperature, hy
chanics, and availability of micronutrients
vestigated. Elevated temperature expe
showed that the rate of reduction in prima
ductivity was greatest in those samples st
to heat above 35 degrees C. For the sample
to or above 50 C, the primary productivity
hours of incubation was less than 0.5 mg/c
was at times close to zero. The productivi
ples from the intake water which had bee
to the temperature of the discharge wa
productivities as high as those of intake
This suggests that although water is wel
after going through the condenser cooling
the water passing through the condenser i
ceives a differential heat, such that a portio
lake water was heated above the toleran
for phytoplankton. Fragments of phytop

Descriptors: *Toxicity, *Fish, *Snails, *Distillery wastes, Industrial wastewater, Effluents, Water pollution effects, Bioassay, Sulfides, Suspended solids.

The LC50 for 12-96 h of a distillery wastewater were determined for Lebistes reticulatus, Lymnaea luteola, Lymnaea acuminata and Viviparus bengalensis in the batch experiment with daily exchange of the medium. The sensitivity of the species increases in the given sequence with values of the LC50,96h of 10.77 to 3.73% proportion of wastewater in the medium. Compared with this, with values of the LC50,48h of 14.06-15.71% after 48 h of exposure there is no significant difference in sensitivity, whereas after exposure for 12 and 24 h the sensitivity grows in the following order: V. bengalensis, L. acuminata, L. luteola, Lebistes reticulatus. Toxicity is obviously primarily determined by the sulfides; with increasing time of exposure also the suspended matter and other factors act toxically. (Author's abstract)

ABSENCE OF SELENATE AVOIDANCE BY FATHEAD MINNOWS (PIMEPHALES PROMELAS),
North Texas State Univ., Denton. Dept. of Biological Sciences.
D. E. Watenpaugh, and T. L. Beitinger.
Water Research, Vol. 19, No. 7, p 923-926, 1985. 1 Fig, 2 Tab, 30 Ref.

Descriptors: *Selenates, *Fathead minnows, *Avoidance, Fish behavior, Selenium, Water pollution effects.

Forty fathead minnows (Pimephales promelas) were individually offered a choice between 'clean' water and water containing selenate in a flow-through, Sprague-type avoidance system. During a control period beginning each trial, fatheads exhibited no significant avoidance of either end of the test chamber. Mean residence times in the two ends equalled 48.8 and 51.2% of total time. Similarly fathead minnows did not avoid selenate at concentrations of 0.3-11.2 mg Se/l in 4 separate trials. Overall, the 40 fish partitioned 48.5 and 51.5% of their time in the selenate and selenate-free ends respectively. These results demonstrate that fathead minnows do not behaviorally avoid harmful concentrations of selenate. (Author's abstract)

SOME OBSERVATIONS ON THE OXYGEN CHANGES IN A LAKE COVERED WITH PISTIA STRATIOTES L.,
Ibadan Univ. (Nigeria). Dept. of Preventive and Social Medicine.
M. K. C. Sridhar, and B. M. Sharma.
Water Research, Vol. 19, No. 7, p 935-939, 1985. 1 Fig, 7 Tab, 19 Ref.

Descriptors: *Water lettuce, *Dissolved oxygen, *Lakes, Eutrophication, Nutrients, Water pollution effects, Hydrogen ion concentration, Aquatic plants, Decomposition.

Water lettuce (Pistia stratiotes) is a common free floating aquatic weed in most of the water bodies in Nigeria. In Oba, the lake under study, this weed at one time covered the whole surface. A bamboo barrier was put across the lake and the weed was removed manually from one zone. The lake is fed by two major streams, one of which is polluted and rich in nutrients. A study was made on the dissolved oxygen levels and pH changes in the lake. The lake generally showed low levels of dissolved oxygen and low pH values. These could be attributed to the incoming organically rich water, coverage of the surface by Pistia plants and to the decomposition of these plants resulting in the formation of sludge at the bottom of the lake. Only on one occasion during rainy season did the dissolved oxygen exceed the natural saturation level. That was probably as a result of algae being washed in. (Moore-IVI)

RESPONSES OF BENTHIC MEIOFAUNA TO LONG-TERM, LOW-LEVEL ADDITIONS OF NO. 2 FUEL OIL,
Rhode Island Univ., Narragansett. Graduate School of Oceanography.
J. B. Frithsen, R. Elmgren, and D. T. Rudnick.
Marine Ecology - Progress Series, Vol. 23, No. 1, p 1-14, 1985. 5 Fig, 3 Tab, 99 Ref.

Descriptors: *Hydrocarbons, *Fuel oil, *Water pollution effects, Ecological effects, Sediments, Fate of pollutants, Benthos.

Three experiments were conducted to investigate the responses of benthic meiofauna to long-term, low-level additions of No. 2 fuel oil in large (13 cu m), outdoor tanks (mesocosms) containing sediment and sea water from Narragansett Bay, Rhode Island. In the first experiment, an average water column oil concentration of 190 ppb was maintained for 168 d followed by a 64 d period of no oil additions. During the second experiment, an average oil concentration of 90 ppb was maintained for 122 d. A 386 d period of no oil additions (Experiment III) followed Experiment II. The abundances of metazoan meiofauna decreased during oil addition periods in Experiments I and II with the oil more extensively affecting the meiofauna in the first experiment. In both experiments, ostracods and harpacticoid copepods were the most sensitive metazoan groups. In contrast, abundances of protozoan meiofauna (foraminiferans and ciliates) were higher in the oiled mesocosms. Abundances of most meiofaunal groups returned to levels similar to the controls within 2 to 7 mo following the termination of oil additions. However, the abundances of kinorhynchs and halacarids remained depressed for more than 1 yr after the last oil addition, presumably due to residual oil in the sediments. (Author's abstract)

EFFECTS OF ENTRAINMENT ON PHYTOPLANKTON PRIMARY PRODUCTION AT FOUR THERMAL ELECTRIC GENERATING

STATIONS ON THE LAURENTIAN GREAT LAKES,
Ontario Hydro, Toronto. Research Div.
T. G. Dunstall.
Internationale Revue der Gesamten Hydrobiologie, Vol. 70, No. 2, p 247-257, 1985. 3 Fig, 3 Tab, 31 Ref.

Descriptors: *Environmental effects, *Electric power production, *Great lakes, *Phytoplankton, *Entrainment, *Laurentian Great Lakes, Cooling water, Primary production, Water temperature, Water pollution effects, Thermal pollution.

Primary production was used to measure the response of phytoplankton to entrainment in once-through cooling water at thermal electric generating stations. Ambient lakewater temperatures ranged from 1.0 to 20.5 C. The maximum discharge temperature was 32.0 C. There was no chlorination of cooling water at the stations studied. On a few occasions, primary production was stimulated following station passage by discharge temperatures which were approximately 10 C above ambient lakewater temperatures of 4.5 to 8.5 C. Differences in production levels were not apparent, however, following the return of discharge water to ambient lakewater temperature. There was no consistent response of phytoplankton to the temperature regimes tested, with production levels generally differing by less than 20% as a result of station passage or temperature elevation alone. Entrainment was considered to have minimal impact on phytoplankton productivity in large open water bodies such as the Great Lakes. (Author's abstract)

EFFECTS OF BENTHIOCARB HERBICIDE ON GROWTH OF PLANKTONIC ORGANISMS, CHLORELLA SACCHAROPHILA AND BRACHIONUS PLICATILIS,
Kagoshima Univ. (Japan). Faculty of Fisheries.
H. Hirata, S. Yamasaki, and E. Kohirata.
Memoirs of the Faculty of Fisheries, Kagoshima University, Vol. 33, No. 1, p 51-56, December, 1984. 3 Fig, 3 Tab, 9 Ref.

Descriptors: *Herbicides, *Benthiocarb, *Toxicity, *Growth, *Chlorella, *Brachionus, Water pollution effects, Ethanol, Pesticides, Zooplankton, Phytoplankton.

The effects of benthiocarb herbicide on the population growth of planktonic organisms were examined to evaluate its toxicity in natural rivers as runoff from rice fields. The organisms used in this experiment were Chlorella saccharophila and Brachionus plicatilis. Concentrations of the herbicide were regulated to sub-acute levels at: 0.0 ppm as control, 0.0003 ppm, 0.01 ppm, 0.03 ppm, 0.1 ppm, and 0.3 ppm. Ethanol was used to dilute the original concentrated benthiocarb. The effects of ethanol on the growth of plankton were also observed. There were no significant differences found among the culture experiments conducted for the growth of C. saccharophila and B. plicatilis below the herbicide concentration of 0.3 ppm. However, in the ethanol experiments, the growth rate of plankton was less than that at a 0.3 ppm herbicide concentration. Careful utilization of ethanol for dilution is suggested for practical use. (Author's abstract)

TOXICITY CURVE ESTIMATION: FITTING A COMPARTMENT MODEL TO MEDIAN SURVIVAL TIMES,
Ortho Pharmaceutical Corp., Raritan, NJ. Dept. of Medical Biostatistics.
R. D. Chew, and M. A. Hamilton.
Transactions of the American Fisheries Society, Vol. 114, No. 3, p 403-412, May, 1985. 6 Fig, 1 Tab, 24 Ref.

Descriptors: *Toxicity curves, *Compartment models, *Toxicology, *Median survival times, Mathematical analysis, Statistical analysis, Data interpretation.

In an acute lethality toxicity test, organisms are continuously exposed to each of several concentrations of the toxicant and subsequent deaths are recorded. The results of the test are often summarized by the toxicity curve, which shows for each concentration the exposure time required to cause exactly 50% mortality. A new statistical procedure for estimating the toxicity curve was developed; it is based on a mathematical model derived from plausible assumptions about the biological mechanisms of acute toxicity. The statistical fit of the model is accomplished by nonlinear, weighted, least-squares regression, estimated median survival times being responses and concentration being the independent variable. The usual methods for constructing a toxicity curve are encumbered by at least one of two weaknesses: either the mathematical form of the curve has no apparent biological justification or the statistical fit of the curve treats concentration as the response and time as the independent variable, thereby reversing the cause-effect relationship. The new method possesses neither of these deficiencies. Analyses of two toxicity tests indicate that the proposed mathematical model is not inconsistent with real data. (Author's abstract)

EFFECTS OF SUBLETHAL COPPER CONCENTRATIONS ON THE STRUCTURE AND ACTIVITY OF ATLANTIC SILVERSIDE SCHOOLS,
Rhode Island Univ., Narragansett. Graduate School of Oceanography.
K. H. Koltes.
Transactions of the American Fisheries Society, Vol. 114, No. 3, p 413-422, May, 1985. 8 Fig, 2 Tab, 46 Ref.

Descriptors: *Copper, *Toxicity, *Water pollution effects, *Silverside, *Fish behavior, Behavior, Metals, Animal behavior.

The effects of sublethal concentrations of copper on the structure and activity of schools of the Atlantic silverside, Menidia menidia, were studied. A computerized video technique was employed to provide three-dimensional analysis. Ten experiments were conducted in which the behavior of a school exposed to from 0 to approximately 100 micro-g/L of copper was compared to the behavior of the same school on the previous day (control). Fish schools exposed to copper differed significantly ($P < 0.05$) from control schools in distance to nearest neighbor, swimming speed, mean direction of travel, rate of change of direction, and depth of the school in the tank. At low concentrations of copper, schools increased their swimming speed, decreased their rate of change of direction and their nearest-neighbor distances, and swam more in parallel orientation than schools under control conditions. PLASMA OSMOTIC AND ELECTROLYTE CONCENTRATIONS OF LARGEMOUTH BASS FROM SOME ACIDIC FLORIDA LAKES,
Florida Univ., Gainesville. Dept. of Fisheries and Aquaculture.
D. E. Canfield, Jr., M. J. Maceina, F. G. Nordlie, and J. V. Shireman.
Transactions of the American Fisheries Society, Vol. 114, No. 3, p 423-429, May, 1985. 3 Tab, 29 Ref.

Descriptors: *Fish physiology, *Bass, *Hydrogen ion concentration, *Florida, Acidity, Acid lakes, Growth, Water pollution effects.

Five acidic clear (pH 3.7-4.9), three acidic colored (pH 4.1-4.6), and three neutral (pH 6.9-7.3) north-central Florida lakes were surveyed in 1983 to determine plasma osmotic and electrolyte concentrations, growth, and coefficients of condition for largemouth bass, Micropterus salmoides floridanus. Plasma osmotic concentrations averaged greater than 273 milli-osmoles/kg in fish from acidic colored and circumneutral lakes, but averaged less than 269 milli-osmoles/kg in four of the acidic clear lakes. Growth and coefficients of condition of largemouth bass > 305 mm total length in the acidic lakes were significantly lower than in the neutral lakes. Reduction in fish growth and condition, however, could be related to either conditions or lake trophic status. (Auth
stract)

ronment. Cells derived from rainbow tro
(RTG-2) and bluegill fry tissues (BF-2) w
as model cell systems to measure cytotoxi
genotoxicity following exposure to Puge
sediment extracts, benzo(a)pyrene and M
nitrosamide). Sediment was collected from
sites within Puget Sound known to be co
ed with compounds such as polycyclic
hydrocarbons, polychlorinated biphenyls,
ated hydrocarbons and heavy metals. Eac
sediment samples was extracted with orga
vents and added to cultures of the two m
systems in DMSO. Following exposure
tures were evaluated for cell death, mitoti

ılatory effects, and chromosomal ese cell cultures responded to the sedi- ts much as they did to known mutagen- enic chemicals which were used as ounds. Those sediments known to be d, based on chemical analysis and his- atterns were also found to be qualita- quantitatively more toxic than were om areas which were relatively unaf- man activity. The results show that in stems are capable of detecting pollu- arine environment and have the poten- powerful tools in aquatic toxicology in with whole animals or as a method of aterials prior to in vivo testing. ogy, Vol. 6, No. 3, p 209-217, 6 Tab, 14 Ref.

Toxicity, *Synergistic effects, yth, *Alchohols, *Chlorinated hy- ructure activity relationships, *Mixtures, Water pollution effects, Chlorobenzenes, Mixture toxicity index, No observable effects concentration, Crustaceans.

The joint effects of mixtures of several similarly acting compounds were assayed in acute and subacute toxicity experiments with several aquatic species. The classification of the several groups was based on quantitative structure-activity relationships (QSARs). A close realtionship indicates a similarity of mode of action for the chemicals within the group studied. Effects on growth of Daphnia magna were studied for 10 non-reactive organic chemicals such as alcohols and chlorobenzenes. The 'no observed effect concentration' (NOEC) was very well correlated with the hydrophobicity (P sub oct) of the tested compounds which appeared in a QSAR study. With this QSAR the NOEC for 15 other compounds was predicted. The joint toxicity of mixtures of 10 and 25 compounds was also tested. The standard deviation in the Mixture Toxicity Index (MTI) was calculated with an estimated standard deviation in log NOEC of 0.10. The NOEC of these mixtures was predictable on the basis of concentration-additivity. It is likely that the small deviations from concentration-additivity are not systematic for mixtures of chemicals with the same modes of action, but are due to a lower reproducibility of experiments with sublethal toxicity criteria such as inhibition of reproduction or growth. Joint levels of mixtures of chemicals with similar modes of action, as indicated by QSAR studies, are concentration-additive. At levels such as NOECs with sublethal toxicity criteria joint toxicity is still present. (Collier-IVI)

Simultaneous studies were conducted on concentrations of chlorinated phenolics (CP) and resin acids (RA) in bleached kraft pulp mill effluents (BKME), their distribution in the receiving water, their uptake and accumulation in the blood plasma of rainbow trout caged in the recipient, as well as short-term physiological effects developed in fish. RA disappeared from the lake water much faster than most of the CP. Some of the BKME-related substances (e.g. 2,4,6-trichlorophenol, 4,5,6-trichloroguaiacol, tetrachloroguaiacol and dehydroabietic acid) were also detected upstream from the mill, thus implying a low-level contamination of this water system in general. In the blood plasma of caged trout free RA were detected up to 3 km from the sewer, but free CP were analyzed as far as 11 km from the mill. During the 10-day caging period a partial inhibition of liver UDP-glucuronosyltransferase was observed even at 11 km from the BKME source. Brain acetylcholinesterase activity showed that BKME did not work like anticholinesterase agents, whereas a decrease of plasma cholinesterase activity was developed in a few days in the nearest 6 km from the sewer. Trout exposed at 6-11 km from the sewer displayed increased blood hemoglobin and decreased plasma protein concentrations. The plasma ionic picture (Na, Cl, Mg) indicated only negligible effects on fish osmoregulation. (Author's abstract)

ENHANCEMENT OF MARINE PRIMARY PRODUCTION BY NITROGEN-ENRICHED ACID RAIN,
North Carolina Univ. at Morehead City. Inst. of Marine Sciences.
H. W. Paerl.
Nature, Vol. 315, No. 6022, p 747-749, 27 June 1985. 3 Fig, 7 Ref.

Descriptors: *Primary production, *Marine environment, *Nitrogen, *Acid Rain, Rain, Nutrients, Water pollution effects, Hydrogen ion concentration, Phytoplankton, Growth.

The effect of acid rain on the pH of freshwater habitats is well known. The acidity of rainwater is largely due to hydrated oxides of sulfur, nitrogen and carbon, which also constitute nutrients essential for plant growth. Most freshwater and marine environments contain sufficient quantities of inorganic carbon and sulfur to satisfy plant growth needs, but nitrogen inputs can at times fall short of growth demands. Nitrogen limitation of phytoplankton growth is widespread and chronic in some marine waters. Nitrogen-limited conditions in North Carolina near-surface waters are ameliorated following rainfall inputs; the most acidic rainfall events led to the greatest stimulation of phytoplankton growth. Continentally-derived acid rain consistently contained more inorganic nitrogen (NO_3^-, NO_2^- and NH_4^+) than near neutral rainfall generated from oceanic fronts. Marine primary production can thus be influenced by the source of rainfall in marginal environments. (Author's abstract)

The relative importance of nutrient loadings and hydrographical and meteorological conditions for oxygen conditions in the Thisted Bredning, Denmark were evaluated by intensive survey and model calculations. The influence of wind speed on the vertical mixing in the unstratified shallow waters was quantified and tested in an oxygen model. The significance of oxygen consuming biological processes on the oxygen conditions were tested. By the use of a eutrophication model, the influence of local discharges of sewage on the size of the oxygen producing and oxygen consuming processes in the Thisted Bredning was calculated. Calculations showed that only a minor increase in rates of the oxygen consuming processes result in a drastic rise in the probability of oxygen depletion. (Author's abstract)

The effects of heavy metals leaching from waste tips at an old copper mine in Bersbo, Sweden, on the levels of cadmium, zinc and copper in the biosphere were investigated in light of plans to drain and cultivate a nearby fenny area which is periodically flooded by runoff water from the tips. Roots from common reed (Phragmites communis) growing in nearby brooks and lakes and from the rush (Juncus effusus) growing on fenny areas that were regularly flooded by contaminated water were analyzed, and the metal concentrations in the hepato-pancreas of crayfish (Astacus fluviatilis) caught in the area were also determined. The waste tips were drained by three different brooks, all of which ultimately reached Lake Risten and further lakes downstream. The metal concentrations in the biosphere in and around the brooks and the lakes were increased up to 20-fold as far downstream as Lake Yxningen, about 15 km from Bersbo. The western part of the fenny area that was to be drained was flooded by a brook that had first passed through a marshy area abundantly overgrown with reeds, where most of the metals were retained; this western area was therefore only slightly contaminated. The eastern part of the fenny area also received a direct flow of metal-contaminated water from another brook, and metal concentrations in this part were therefore much higher. (Author's abstract)

Pathological changes in the kidney as a result of exposing the teleost Puntilus conchonius to acutely lethal and sublethal concentrations of the organophosphate insecticide monocrotophos are reported. The release of fish into monocrotophos solutions immediately resulted in very fast and erratic swimming which calmed down to normal movements within 2-3 hr. In acutely lethal concentrations, the initial excitement was accompanied by occasional jumping. Externally, the kidneys of acutely as well as sublethally treated fish were swollen and enlarged in comparison to their normal size. In acute concentration, some significant changes were noted in the kidneys of P. conchonius. Within 24 hr, the glomeruli of the majority of Malpighian corpuscles had undergone a marked contraction so that a prominent gap was seen between them and the capsular walls. In sublethal bioassay, as early as 2 days post exposure, vasodilation and tubular atrophy by way of hydropic vacuolation in the cells had become quite evident. Monocrotophos appears to be a stronger nephral poison than formothion for fish as, besides hydropic degeneration of tubules, it also caused glomerular contraction, vasodilation and dissolution of lymphodial tissue to form blood-sinuses. EFFECT OF ANILINE ON CHLORELLA VULGARIS,
North Carolina State Univ. at Raleigh. Dept. of Zoology.
H. M. Ammann, and B. Terry.
Bulletin of Environmental Contamination and Toxicology, Vol. 35, p. 234-239, August, 1985. 3 Fig, 8 Ref.

Descriptors: *Aniline, *Algae growth, *Chlorella, *Water pollution effects, Organic compounds, Industrial wastes, Dye industry wastes, Respiration, Photosynthesis.

Release of hazardous waste into the aquatic ecosystem produces a variety of complex responses beyond lethality to specific organisms. Hidden injury, such as inhibition of photosynthesis, or changes in oxygen consumption, must significantly affect the role that a primary producer plans in the food pyramid. Threshold concentrations of aniline (a component of dye industry effluents) which affect growth of algae are established. Results show that aniline not only significantly affects growth of Chlorella vulgaris, but also affects respiration and photosynthesis. Comparison of the growth curve with oxygen consumption at 255.5 ppm may explain decreased oxygen consumption as a factor in decreased population density. However, the decline in rate of photosynthesis occurred at an aniline concentration (173.44 ppm) below that considered critical for growth. Since Federal standard emphasize effects on growth as a primary determinant in establishing exposure limits for aquatic organisms to chemical compounds it seems obvious that this is not the only parameter to be measured if aquatic ecosystems are to be preserved. Primary producers would be eliminated over time through sub-lethal exposures with subsequent severe damage, if not elimination of entire food pyramids. (Baker-IVI)

lutants present in the wastewater
ial plant producing surfactants and
other chemicals used in the textile, leather and cosmetic industries are detergents, oily emulsions, sulfates and organics. Laboratory investigations show that the removal efficiencies for detergents and oily emulsions are high when the wastewater is treated in a two-stage process consisting of chemical precipitation with barium chloride and alum coagulation. The coagulation may also involve the addition of sulfates in order to provide for a complete removal of barium ions. The effluent is clarified and colorless, and the concentrations of pollutants present comply with the required standards. An advantage to the use of barium chloride is that the detergents and oily emulsions present in the wastewater are precipitated. Sulfates, which occur at concentrations above the admissible levels, are also subject to precipitation. Oil spills can be successfully removed with polyurethane foams characterized by a high sorbing capacity. (Moore-IVI)

DESIGN AND OPERATION OF BARDENPHO PLANTS IN AN AFRICAN COUNTRY,
Meiring and Partners, Pretoria (South Africa).
J. L. Barnard.
Water Pollution Control, Vol. 83, No. 4, p 443-449, 1984. 4 Fig, 3 Tab.

Descriptors: *Wastewater treatment, *South Africa, *Bardenpho process, Nutrient removal, Design criteria, Biological wastewater treatment, Operation, Phosphates, Aeration.

The suitability of the Bardenpho process for nutrient removal prior to discharge to stream was investigated in South Africa for sewage treatment. Unfortunately, the plants were operated with a minimum of analytical data. The COD:Total N ratio of the crude sewage for all plants was favorable, being mostly about 12:1. This may decrease to below 10:1 after primary sedimentation. The type of design used for the rural plant No. 2 is in many ways similar to channel type plants but has several other advantages: the aeration basin could be much deeper and the plant more compact, vertical spindle surface aerators could be used in the Carousel system allowing for larger individual units to be used; aeration and denitrification could be controlled simply by switching aerators in and out using timers and by manual weir control, the aerators could be concentrated towards the outlet of the basin thus ensuring that a good aerated regime exists before the final clarifier and a high degree of nitrification is achieved with good denitrification, a quick turn around of the bacterial mass to the anoxic zone, and overall simplicity of the system. While it is sometimes felt that it takes less skill to operate a biological filter plant with chemical additions for phosphate removal, this could be true only if no attention is paid to cost and to secondary pollution that results, as all that is required is to overdose the plant in order to precipitate phosphates. TREATMENT OF WASTE WATER FROM THE LEATHER INDUSTRY,
Leather Industries Research Inst., Grahamstown (South Africa).
D. R. Cooper, S. G. Shuttleworth, and N. P. Slabbert.
Water Pollution Control, Vol. 83, No. 4, p 450-454, 1984. 7 Tab.

Descriptors: *Tannery wastes, *Wastewater treatment, *Industrial wastes, Aeration, Flotation, Activated sludge process, *Biological wastewater treatment, Chromium, Sulfides, Suspended solids, Effluents.

Possible suggestions are offered for the treatment of effluent from a chrome leather tannery. For mixed tannery effluent, all process liquors should be balanced and aerate in balancing tanks for 24 hr to remove sulfide. This effluent would not be suitable for municipal discharge because of high concentrations of SS, settleable solids and chromium content. Physico-chemical treatment involves ferric chloride and polyelectrolyte dosing plus air flotation. This effluent should be suitable for municipal discharge since most of the chromium would have been removed together with the suspended solids. The lower oxygen demand of the treated effluent will ensure acceptability of the effluent as far as organic content is concerned. Only the inorganic levels, as reflected by the total dissolved solids (mainly inorganics), sulfate and chloride contents, could possibly exceed the discharge limits of some municipalities. Further organics removal could be obtained by biological treatment, by activated sludge or high rate filter. A stepwise treatment, i.e. physico-chemical followed by biological treatment, is better and easier for highly-polluted tannery effluents than a single activated sludge process. Fresh water discharge would still not be possible since with even the best available effluent treatment of tannery effluents, the general/special standards for rivers will not be met. (Baker-IVI)
W86-01016

POTENTIAL OF ANAEROBIC DIGESTION FOR TREATING LIQUID WASTES,
Birmingham Univ. (England). Dept. of Civil Engineering.
C. G. Forster.
Water Pollution Control, Vol. 83, No. 4, p 484-490, 1984. 7 Fig, 2 Tab, 26 Ref.

Descriptors: *Wastewater treatment, *Anaerobic digestions, Industrial wastes, Evaluation, Anaerobic expanded bed process, Biological wastewater treatment.

The potential for using anaerobic digestion as a method for treating liquid wastes was examined. Laboratory scale digesters have been shown to be useful in evaluating the compatibility of a process and a particular effluent. Design options that are available are considered along with design criteria which must be met. The results indicate that the anaerobic expanded bed (AEB) process exhibits a large degree of dispersion irrespective of the hydraulic retention period being used. In other words, the system is well-mixed. No short circuiting was occurring. The data also indicates that the AEB system, and probably other types of anaerobic digesters, is not a suitable method for the treatment of effluents with a strength as low as that of normal domestic sewage unless it is considered merely as a roughing process. This study also showed an additional and interesting point. On a number of occasions air entered the system, either when pump tubing failed or when the bed had to be opened for minor repairs. This did not appear to have any significant effect on the performance indicating that, contrary to most of the literature, the anaerobic microbial flora is extremely robust. (Baker-IVI)
W86-01018

APPLICATION OF ANAEROBIC PACKED-BED REACTORS TO INDUSTRIAL WASTE-WATER TREATMENT,
Newcastle upon Tyne Univ. (England). Public Health Engineering Div.
G. K. Anderson, K. J. McKeown, and T. Donnelly.
Water Pollution Control, Vol. 83, No. 4, p 491-498, 1984. 1 Fig, 3 Tab, 13 Ref.

Descriptors: *Anaerobic digestion, *Industrial wastes, *Packed bed reactors, Filters, Filtration, Biodegradation, Biological wastewater treatment.

The treatment of organic waste waters by anaerobic packed-bed reactors offers considerable advantages over other types of anaerobic treatment systems. They have been proven over a wide range of industrial waste waters with considerable variation in concentration of organic matter. The reactors are able to maintain a high biomass concentration with attachment of both acidogenic and methanogenic bacteria. This enables a high BOD load to be applied while concurrently offering stability under varying load conditions and inhibitive conditions. Careful research and design can optimize treatment efficiency and methane production and, together with control of sulfide production in the appropriate situations, it is anticipated that a wide range of wastewaters will be treated by this method. (Baker-IVI)

ANAEROBIC TREATMENT OF WASTE WATERS IN THE BEET SUGAR INDUSTRY,
British Sugar Corp. Research Labs., Norwich (England).
M. Shore, N. W. Broughton, and N. Bumstead.
Water Pollution Control, Vol. 83, No. 4, p 499-506, 1984. 4 Fig, 3 Tab, 22 Ref.

Descriptors: *Anaerobic digestion, *Wastewater treatment, *Food processing industry, Beets, Industrial wastes, Water reuse, Methane, Fuel.

Beet sugar production requires substantial volumes of water, but in modern beet sugar factories most of it is recycled. The theoretical volume of effluent at the British Sugar factory at Bury St. Edmunds exceeds 100 tcmd, but treatment and re-use have reduced this to only 4.8 tcmd. Most of this originates from incoming water in the beets which is not eliminated either in the end-products or in evaporation to atmosphere. Anaerobic processes developed in the last decade specifically for the beet sugar industry have the advantages of a much lower input energy cost and production of the valuable fuel methane to offset their high capital cost. The four main methods of anaerobic treatment in general use in the industry are the Anamet, IRIS, Anodek, CSM processes. The Anamet plant commissioned at Bury St. Edmunds factory during the 1982-1983 processing season is described. During the last three of the five weeks operations for which results are available, the plant routinely removed about 90% of the influent COD and had a daily methane production which, maintained for a full processing season, would be worth more than 22,000 pounds as a fuel oil replacement. When fully operational, the plant is expected to yield methane worth nearly three times this amount from the removal of more than 16 t COD/day. (Baker-IVI)

Gas production from the farm digester treating animal slurries could be boosted at times by adding to the slurry silage liquid (a potential cause of heavy pollution of water courses), and crop wastes. Waste vegetable matter would have to be macerated before it could be pumped with slurry. Maximum use of all products of digestion is desirable and uses of digested slurry other than for fertilizer are envisaged and are being tested. A protein, or protein plus ammonia, nitrogen supplement to farm animal feeds is a possibility. A problem arises due to the large liquid volume of the slurry. A suitable, low-cost, low-energy method of concentrating and drying the slurry solids containing the bacterial protein has not yet been devised. Making silage could be a way of mopping up the liquid, or mixing with grain to form a liquid feed is also possible. Hydroponics, fish farming, growing of worms or algae, are all possible uses for digested slurries; experiments on these and other uses are being carried out. (Baker-IVI)

EXPERIENCE WITH THE ANODEK PROCESS,
Dunlop Bioprocess, Birmingham (England).
G. G. Morris, and S. Burgess.
Water Pollution Control, Vol. 83, No. 4, p 514-520, 1984. 1 Fig, 10 Tab, 5 Ref.

Descriptors: *Anodek process, *Methanogenesis, *Anaerobic digestion, Methane bacteria, Acetogenic bacteria, Biological wastewater treatment, Biogas.

Anaerobic digestion is usually achieved in one step with the entire process (acidogenesis and methanogenesis) taking place in one reactor. The two stage Anodek process is based on the fact that the methanogens can only utilize a limited number of intermediates. These are methanol, hydrogen, formate and acetate. The methanogens have to directly remove the hydrogen produced by the obligatory hydrogen producing acetogenic (OHPA) bacteria in order to favor the thermodynamic conditions for growth of their syntrophes, the OHPA bacteria. Therefore, technically the OHPA bacteria and the methanogens have to exist in physical proximity, hence in one particular reactor. In practical terms Anodek is a method for the production of methane gas and the treatment of aqueous solutions of organic compounds by means of a two stage anaerobic fermentation process. The first stage is used to solubilize/hydrolize the effluent and provide the second stage with an optimum of constant feed by various means. The second stage is a methane reactor where methane gas is produced from the conditioned feed. About 70% of the COD present in the wastewater can be rapidly converted into biogas, representing a 95% BOD reduction. (Baker-IVI)

LEACHATE TREATMENT WITH PARTICULAR REFERENCE TO AERATED LAGOONS,
Water Research Centre, Stevenage (England).
P. J. Maris, D. W. Harrington, and G. L. Chismon.
Water Pollution Control, Vol. 83, No. 4, p 521-538, 1984. 7 Fig, 13 Tab, 36 Ref.

Descriptors: *Leachates, *Wastewater treatment, *Aerated lagoons, Landfills, Clarification, Aeration, Waste disposal, Biological wastewater treatment, Chemical treatment, Sludge.

The development of scientific landfill management will lead to increasing constraints on leachate disposal. Leachate has particular problems notably organic strength, metals and high ammonia N content. The age and the method of emplacement of the waste play an important part in determining the nature of the leachate. Leachates from recently emplaced wastes are amenable to biological treatment while leachate from more aged waste which contains more refractory compounds may need both chemical and biological treatment. Aerobic treatment of leachate will give rise to a large quantity of sludge which will require thickening and disposal. The volume of leachate produced from a landfill will be dependent upon climatic conditions, the rate of infiltration and the degree of compaction of waste. The most effective way of reducing the volume of dump leachate is by good site engineering and management. Leachate is deficient in phosphorus, which, for effective biological treatment, must be added as a nutrient supplement. The most effective biological treatment is aerated lagooning, followed by clarification. Other options include chemical treatment, the anaerobic process, activated-sludge treatment and rotating biological contactors. Aeration of strong leachate produces large volumes of sludge. This settles readily and may be thickened up to 5.6-7.7% dissolved solids. It is imperative that the treatment process should be simple, reliable and require low maintenance and operating expertise. Adsorption at solid-solution interfaces is an important means of controlling the extent of pollution due to metallic species in industrial effluents, but the use of activated carbon is not suitable for developing countries due to its high cost. The use of fly ash from thermal powerplants as an adsorbent for the removal of Cu(II) for aqueous solutions was studied and 100% removal was noted when the solution concentration was initially at 1.0 x 10 to the -4 M. The removal of Cu(II) by adsorption on fly ash is concentration, pH and temperature dependent. The kinetics of adsorption indicates the process to be diffusion controlled. The Langmuir constants were calculated at different temperatures, and the adsorption was found to be endothermic (delta H = 15.652 kcal/mol). The maximum removal is observed at pH 8.0. The hydrolyzed species of Cu(II) are involved in complexation with surface active sites of fly ash. (Moore-IVI)

PERSISTENT CHEMICALS IN PULP MILL EFFLUENTS OCCURRENCE AND BEHAVIOUR IN AN ACTIVATED SLUDGE TREATMENT PLANT,
Eidgenoessische Anstalt fuer Wasserversorgung, Abwasserreinigung und Gewaesserschultz, Duebendorf (Switzerland).
C. Leuenberger, W. Giger, R. Coney, J. W. Graydon, and E. Molnar-Kubica.
Water Research, Vol. 19, No. 7, p 885-894, 1985. 5 Fig, 5 Tab, 37 Ref, 1 Append.

Descriptors: *Pulp wastes, *Activated sludge process, *Chlorinated hydrocarbons, Wastewater treatment, Chlorinated phenols, Chloroform, Chlorinated terpenoids, Chlorinated resin acids, Adsorption, Water pollution, Switzerland.

In wastewater effluents of a Swiss pulp mill more than 50 organic chemicals were identified including chlorinated phenols, chloroform, chlorinated terpenoids and chlorinated resin acids. Quantitative determinations were carried out to investigate the behavior of the most abundant constituents during wastewater treatment in an activated sludge process. In particular, the chlorinated compounds were only partly eliminated. The lipophilic chlorinated phenols were physically absorbed to some extent into the activated sludge biomass. The importance of this nonbiological elimination mechanism was evaluated by applying distribution coefficients between activated sludge particles and water which were determined for a series of chlorinated phenols. Chloroform and other purgeable compounds were removed mainly by transfer into the ambient air. The impact of the persistent wastewater constituents on the water qualtity in the receiving River Aare was assessed. It was estimated that the concentrations of chlorinated phenols in the river caused by the discharge of the treated pulp mill wastewater are about 10 time lower than the levels of pentachlorophenol which typically occur in Swiss rivers receiving effluents from municipal wastewater treatment plants. LEACHATE TREATMENT WITH NITRIFICATION OF AMMONIA,
Cleanaway Ltd., Rayleigh (England).
K. Knox.
Water Research, Vol. 19, No. 7, p 895-904, 1985. 8 Fig, 5 Tab, 11 Ref.

Descriptors: *Landfill leachates, *Wastewater treatment, *Nitrification, *Ammonia, Leachates, Activated sludge process, Trickling filters, Biological wastewater treatment, Organic carbon, Temperature effects, Seasonal variation.

Small outdoor activated sludge and trickling filter plants were operated for 2 years to investigate nitrification in a leachate from a long-established co-disposal landfill. There has been little long-term change in leachate quality at the site, but seasonal fluctuations were observed. Leachate ammonia nitrogen concentrations ranged from 150 to 550 mg/l while total organic carbon (TOC) concentrations ranged from 200 to 500 mg/l. This suggested that NH3-N concentrations were influenced by factors additional to those which produced the variations in TOC concentrations. Very little of the TOC was degradable and BOD:NH3-N ratios were typically 1:3. In the activated sludge plant, clarification was poor. This was at least partly attributed to the low BOD:NH3 ratio. Fewer problems of this sort occurred in the biological filter. Nitrification was successfully established in both plants, and curves were established for the response of the kinetics to different temperatures. The highest ammonia removal rate achieved in the activated sludge plant was 131 g N/kg VSS/day achieved at an average temperature of 13 C. The maximum removal rate in the trickling filter was 309 mg N/sq m/day, at 16 C. This is similar to nitrification rates reported for sewage at similar temperatures. The sensitivity of the process to temperature and the disproportionate production of leachate in winter months indicate that full-scale plant design would be optimized if leachate were stored on-site during winter months for treatment during warmer weather. EPIDEMIOLOGICAL EVIDENCE FOR HELMINTH AND CHOLERA TRANSMISSION BY VEGETABLES IRRIGATED WITH WASTEWATER: JERUSALEM - A CASE STUDY,
Hadassah Medical School, Jerusalem (Israel). Environmental Health Lab.
H. I. Shuval, P. Yekutiel, and B. Fattal.
Water Science and Technology, Vol. 17, No. 4/5, p 433-442, 1985. 3 Fig, 11 Ref.

Descriptors: *Wastewater irrigation, *Epidemiology, *Cholera, *Parasites, *Jerusalem, *Israel, Public health, Diseases, Wastewater disposal, Wastewater treatment, Water reuse, Pathogens, Agriculture.

This paper reviews and reanalyzes epidemiological data on the transmission of the helminthic diseases ascariasis and trichuriasis as well as cholera by vegetables and salad crops irrigated with untreated wastewater in Jerusalem between 1935 and 1982, based on a series of published papers and unpublished reports not generally available to professionals in the field of water pollution control. The findings provide strong evidence that both Ascaris and Trichuria infections were actively and massively transmitted to the general public who consumed vegetables irrigated with raw wastewater. The levels of infection dropped dramatically when the supply of contaminated vegetables was cut off but increased again rapidly on reintroduction of the wastewater-irrigated crops. The infection level subsided again when the practice was finally stopped in 1970. The epidemiological evidence from the 1970 cholera outbreak in Jerusalem indicates that wastewater-irrigated vegetables were the primary route of secondary infection once a few subclinical or clinical cases of cholera entered the city from areas outside the country where a cholera epidemic was underway. The evidence also indicates that farmers in an area where cholera is not endemic are particularly at risk when practicing irrigation with raw wastewater from a city undergoing a cholera outbreak. The need to treat wastewater to remove these pathogens prior to the irrigation of such vegetable crops is stressed. (Author's abstract)

WASTEWATER TREATMENT BY ARTIFICIAL WETLANDS,
Ecological Research Associates, Davis, CA.
R. M. Gersberg, B. V. Elkins, and C. R. Goldman.
Water Science and Technology, Vol. 117, No. 4/5, p 443-450, 1985. 5 Fig, 1 Tab, 10 Ref. EPA grant CR-807299-03-0, California Department of Water Resources grant B-53459 AM IV.

Descriptors: *Wastewater treatment, *Artificial wetlands, *Wetland treatment, Secondary wastewater treatment, Advanced wastewater treatment, Nitrogen removal, Biochemical oxygen demand, Suspended solids, Costs.

This report describes studies of artificial wetlands at Santee, California which demonstrate the capacity of these systems for integrated secondary treat-

ment (BOD and suspended solids removal) and advanced treatment (nitrogen removal) of municipal wastewater effluents. When receiving a blend of primary and secondary wastewaters at a blend ratio of 1:2 (6 cm per day 1 degrees: 12 cm per day 2 degrees), mean removal efficiencies for a complete year of operation from July, 1982 through July, 1983 were 80% for total nitrogen (TN) and 80% for total inorganic nitrogen, with the mean inflow TN level of 21.5 mg/l reduced to a mean value of 4.3 mg/l in the wetland effluent. The BOD and suspended solids removal efficiencies were 93% and 88% respectively. The mean wetland effluent values for both BOD and suspended solids were below the 10/10 mg/l standard for advanced secondary treatment. When primary effluent was the sole source of inflow to the artificial wetlands, BOD and suspended solids levels approaching the quality of a secondary treated effluent (30/30 mg/l) could be attained at an application rate of 6-8.3 cm per day. In this case, mean BOD and suspended solids removal efficiencies for the complete year from July, 1982 through August, 1983, were 78% and 80% respectively, with the effluent levels reduced to mean values of 33 mg/l for BOD and 10 mg/l for suspended solids. At the application rate of 6 cm per day, the study shows that only 16 acres (6.5 ha) of the constructed wetlands would be required to treat 3785 cu m of primary wastewaters to secondary treatment levels. Data on capital, and operating and maintenance costs show that artificial wetlands are competitive with other treatment technologies available to small to medium sized communities. USE OF PERACETIC ACID IN OPERATIONAL SEWAGE SLUDGE DISPOSAL TO PASTURE,
Interox Chemicals Ltd., Widnes (England).
J. A. L. Fraser, A. F. Godfree, and F. Jones.
Water Science and Technology, Vol. 17, No. 4/5, p 451-466, 1985. 1 Fig, 8 Tab, 50 Ref.

Descriptors: *Peracetic acid, *Disinfection, *Sludge disposal, Salmonella, Parasites, Pathogens, Pastures, Sludge treatment, Bacteria.

Intestinal pathogens and parasites are a problem associated with the disposal of sewage sludge to pasture. Those of major importance are ova of the beef tapeworm (Taenia saginata) and Salmonella bacteria. Techniques for routine monitoring of pathogens and intestinal parasite levels in sludge together with design of simple methods for their removal have intensified, because disposal of sewage sludge to pasture is coming under increasing international surveillance. The performance during field trials of a proprietary peracetic acid compound (containing 36 to 40% w/w peracetic acid), hereafter referred to as PAA (100%), is described. These trials under operational conditions showed it to be a suitable bacterial and ovicidal agent for the disinfection of raw, digested and activated sludges. Concentrations ranging from 250 to 1000 mg PAA/l have achieved up to 99% inhibition of hatching and up to 100% destruction in viability of tapeworm embryos suspended in raw and digested sludges. Similarly these concentrations resulted in 5 log, reduction in salmonellae seeded in raw sludge. A dose of 250 mg PAA/l reduced salmonellae levels from 4600 organism/100 cu cm to < 30/100 cu cm during gravity thickening of surplus activated sludge. Results from 46 tanker loads of consolidated surplus activated sludge revealed that salmonellae levels were reduced from 2400 organisms/100 cu cm to < 30/100 cu cm at doses of 500, 400 and 300 mg PAA/l. At a lower dose of 150 mg PAA/l levels were reduced to within a range of < 30 to 430 organisms/100 cu cm. At optimum disinfection concentrations for the destruction of both bacteria and parasites, PAA was rapidly utilized resulting in safe, readily biodegradable, non-toxic residuals. The technical and practical benefits, principals of disinfecting sludge and ecological safeguards are highlighted in this paper. Use is made of case histories to describe practical operating techniques. (Author's abstract)

SETTLING OF NUTRIENT REMOVAL ACTIVATED SLUDGES,
Johannesburg City Health Dept. Labs. (South Africa).
A. R. Pitman.
Water Science and Technology, Vol. 17, No. 4/5, p 493-504, 1985. 5 Fig, 3 Tab, 22 Ref.

Descriptors: *Activated sludge, *Sludge settling, *Aeration, Biological wastewater treatment, Nutrient removal, Dissolved oxygen, Clarifiers, Sedimentation, Sludge age.

The successful operation of the activated sludge process is greatly dependent on final clarifier performance. Final clarifier perfomance is related to activated sludge settling properties and these in turn are usually affected by operating conditions in the biological reactor. The settling properties of activated sludges from four biological nutrient removal plants were surveyed. Activated sludge settling properties showed a fair degree of variability with the two extended aeration plants exhibiting superior settling properties in comparison to the two Phoredox/Bardenpho units. One sludge had poor settling properies due to the presence of excessive filamentous growths. Settling properties could be correlated well with the degree of aeration of the activated sludge. Plants operated with an aerobic sludge age greater than 50% of the total sludge age and with aerobic zone dissolved oxygen levels above 1.0 mg/l tended to produce better settling sludges. Empirically derived constants used in the settling flux theory are correlated with more traditional measures of settling properties. An easy method of using the settling flux approach to clarifier design and operation is presented and a new parameter describing the settling properties of sludges is proposed. (Moore-IVI)

SLUDGE CONDITIONING: EFFECTS OF SLUDGE BIOCHEMICAL COMPOSITION,
Oklahoma Univ., Norman. School of Civil Engineering and Environmental Science.
P. T. Bowen, and T. M. Keinath.
Water Science and Technology, Vol. 17, No. 4/5, p 505-515, 1985. 2 Fig, 6 Tab, 25 Ref.

Descriptors: *Sludge conditioning, *Chemical composition, Sludge drying, Carbohydrates, Protein, Lipids, Polymer Index, Biopolymers, Bioflocculation.

Variations in response of three different sludges to conditioning with organic polyelectrolytes were evaluated with respect to the carbohydrate, protein and lipid content of the sludges. These biochemicals comprise the surfaces of most sludges. The difference in the concentration of these compounds is intrinsic to the sludge type. Polymer Index (PI), a measure of minimum polymer dose required to achieve maximum dewaterability, was statistically related to each of the three components. Carbohydrate content correlated most strongly with PI. As carbohydrate content increases, PI was found to decrease indicating better polymer performance. Biopolymers, which are composed mainly of carbohydrates may surround the cells forming a highly reactive surface. These exocellular materials also promote bioflocculation. Both actions result in a lower polymer requirement for destabilizing the sludge. Protein and lipid were not observed to have strong correlation with PI. Cellular surfaces and structures are composed of these components. The low correlation indicates these components are less favored than carbohydrates for polymer interaction. (Author's abstract)

resented represents results of a re-v method for using solar energy for industrial wastewater treatment. eeks to develop economical meth-fection and detoxification of hich would result in the reuse of effluents for crop irrigation. Aerated effluents containing dye-sensitizers were exposed to solar irradiation for various periods of time. The influence of the solar energy, absorbed by these sensitizers in the visible range, on the organic matter and anionic surfactants (MBAS) in secondary effluents was checked by determining the COD and MBAS values of treated wastewater. The disinfection potential of this method was followed by bacteriological analyses of running water or secondary effluents, previously contaminated or enriched, respectively, with laboratory cultures of E. coli, bacteriophages (coliphage X and F2) and polio virus (type L-Sc 1). The influence of this photooxidative method was also studied in eutrophic algae present in the Lake of Galilee. It was found that the conditions under which disinfection proceeds also support algicidal processes, causing lethal damage to algal cultures. Further investigations on stable pesticides (uracil, s-triazine and anilide derivatives) in surface water or industrial wastewater showed that such a method can also be used for detoxifying pesticides in these waters. SYNTHESIS MODELING OF MUNICIPAL WASTEWATER TREATMENT SYSTEMS,
Universidade Nova de Lisboa (Portugal). Sanitary Engineering Group.
A. S. Camara, C. W. Randall, and L. C. Frair.
Water Science and Technology, Vol. 17, No. 4/5, p 633-644, 1985. 2 Fig, 2 Tab, 14 Ref.

Descriptors: *Wastewater treatment, *Optimization, *Model studies, Economic aspects, Costs, Engineering, Tertiary treatment, Efficiency.

The synthesis of wastewater treatment systems refers to the specification of both a system structure, the choice and arrangement of unit processes and operations, and the design of the individual units within that structure so that a set of economic and environmental objectives is fulfilled. Synthesis models allow one to define the minimal cost design for a wastewater treatment system, specifying the system structure and the design of the individual units within that structure. There are still important limitations on cost and engineering data which do not permit a truly optimal design of treatment plants. The major problems in the cost information occur in the tertiary treatment stage. Most of the cost functions of tertiary treatment units are expressed in terms of the plant flow rate and are therefore not related to design variables. As a result, one can not determine optimal dimensions for those units. The main deficiencies in the engineering information are basically in three areas: removal efficiency values for pollutants for most of the tertiary units and some of the secondary units; definition of quantitative relationships between the efficiency of the thickening units and the subsequent digesting and dewatering units; and computation of supernatant flow rate and concentrations. Despite these limitations, it is possible to develop a synthesis model representing an improvement over the available synthesis models. The treatment plant can be considered as a network with loose connections. These weak links allow one to divide it into sub-networks. The synthesis problem is then divided into sub-problems connected by 'tear contraints' (on to each sub-network) and solved using known optimization methods. (Moore-IVI)

TREATMENT OF AGRO-INDUSTRIAL WASTES USING WATER HYACINTH,
Rubber Research Inst. of Malaya, Kuala Lumpur (Malaysia).
C. K. John.
Water Science and Technology, Vol. 17, No. 4/5, p 781-790, 1985. 3 Fig, 4 Tab, 14 Ref.

Descriptors: *Water hyacinth, *Biological wastewater treatment, *Industrial wastewater, Malaysia, Rubber industry, Palm oil mill effluent, Wastewater treatment, Wastewater lagoons.

In Malaysia lagoon systems have been successfully adopted by the natural rubber (NR) and oil palm industries to treat their effluents. The possibility of using Eichhornia crassipes (water hyacinth) in the lagoons to further improve the treatment system was investigated. Good removal of pollutants from the block rubber effluent was achieved using a hydraulic retention of 10 - 15 days. The resulting effluent discharge was of acceptable quality. Water hyacinth also markedly improved the quality of the effluent from the remilling rubber factories. Consequently propagation of water hyacinth in the lagoons has been recommended. Pilot plant trials with palm oil mill effluent (POME) have shown that water hyacinth can be successfully grown in anaerobically digested liquor removing 96% BOD, 87% COD, 96% suspended solids, 83% ammoniacal nitrogen and 97% oil and grease. It also removed more than 99% of the indicative bacteria such as coliforms, Escherichia coli and Streptococci. Under the Malaysian conditions, water hyacinth grew profusely yielding about 500 kg of dry matter per ha per day. The average dry weight was about 5.0% and it contained about 24% protein, 21% fiber and 14% ash. (Author's abstract)

SELECTIVE CULTIVATION OF EASILY HARVESTABLE ALGAE USING CROSSFLOW-MICROSCREENING,
Pretoria Univ. (South Africa). Dept. of Water Utilisation Engineering.
W. A. Pretorius, and L. C. Hensman.
Water Science and Technology, Vol. 17, No. 4/5, p 791-802, 1985. 14 Fig, 1 Tab, 15 Ref.

Descriptors: *Biological wastewater treatment, *Algae, *Crossflow-microscreening, Biomass, Stigeoclonium, Wastewater treatment, Algal harvesting.

The implementation of algal systems as a viable wastewater treatment option has been seriously limited by the availability of cost effective techniques for removing algae from the effluent stream. In this study, the problem of biomass separation was overcome by the selective cultivation of algae species which could be removed effectively by simple screening. The selection of desired species was achieved by a combination of short hydraulic space time and various size microscreens operating as algae selectors on the effluent stream. A high rate algae growth system, in which the mean cell residence time and hydraulic space time could be manipulated independently, was developed. With humus tank effluent as feedstock, a hydraulic space time of 10 hours and a 200 micro-m opening size crossflow-microscreen, the filamentous green algae, Stigeoclonium, became the dominant species. This selected culture could be readily maintained at any predetermined concentration in the system with less than 20 mg/l suspended solids in the effluent. The biomass produced was exceptionally easy to harvest. (Author's abstract)

WASTE WATER RECYCLING BY DUCKWEED FOR PROTEIN PRODUCTION AND EFFLUENT RENOVATION,
Ben-Gurion Univ. of the Negev, Sde Boker (Israel). Jacob Blaustein Inst. for Desert Research.
G. Oron, L. R. Wildschut, and D. Porath.
Water Science and Technology, Vol. 17, No. 4/5, p 803-817, 1985. 6 Fig, 4 Tab, 31 Ref.

Descriptors: *Wastewater renovation, *Duckweed, *Biological wastewater treatment, Water reuse, Aquaculture, Wastewater ponds, Biomass production, Arid areas, Evaporation.

The success of a wastewater recycling system ultimately depends upon the quality of the renovated effluent, mainly for irrigation in dry areas, and on the quality and quantity of the additional by-prod-

ucts accepted. The simultaneous treatment of wastewater and the production of duckweed in a pond system, as an alternative protein source, is an attractive proposition for solving the feed and water shortage problem in arid areas. Outdoor experiments conducted in mini-ponds showed that duckweed ponds may be highly competitive with existing secondary treatment methods. Duckweed systems for secondary wastewater treatment can be highly productive with a biomass yield of 8 to 15 g/sq m per day (dry weight) and crude protein content in the range of 30 to 45% of the dry weight. The ease of the duckweed harvesting makes the system even more economically attractive, and the amino acid composition of the duckweed makes it a good alternative protein source. The removal efficiency of the major pollutants reaches 50 to 60%. The duckweed pond systems are superior to other wet free surface waste treatment methods in regards to water losses. At least 30% of water loss due to evaporation in other wet processes can be saved in duckweed ponds. In areas with limited water sources, this aspect is essential. (Moore-IVI)

POTENTIAL TREATMENT ALTERNATIVE FOR SWINE WASTEWATER IN THE TROPICS,
Hawaii Univ. at Manoa, Honolulu. Dept. of Agricultural Engineering.
P. Y. Yang, and S. Y. Nagano.
Water Science and Technology, Vol. 17, No. 4/5, p 819-831, 1985. 7 Fig, 9 Tab, 14 Ref. EPA grant R-808056.

Descriptors: *Animal wastes, *Tropical areas, *Biological wastewater treatment, Anaerobic digestion, Algal biomass raceway, Methane, Wastewater management, Energy production.

Development of a low-cost and effective swine waste management system in the tropics is the main objective of this study. Because of the appropriate temperature environment and abundance of sunlight, an integration of an anaerobic digestion and an algal biomass process was selected and investigated. A pilot plant integrating a 20 cu m anaerobic digester with sludge recycling and a 120 cu m algal-biomass raceway were installed and evaluated. Maximum gas production rate of 1.527 liter/liter/day (69% methane content) can be achieved by the total volatile solids (TVS) loading rate of 4.23 gram/liter/day. A sludge production rate of 0.82-2.62 g total solids/liter is obtained from a TVS loading rate of 0.76-4.23 g TVS/liter/day. Critical solids retention time for maximum gas production rate is 2.67. For the algal biomass raceway, a loading rate of 0.097 g soluble COD/liter/day or 0.017 g NH4-N/liter/day would achieve soluble COD and NH4-N removal efficiencies of 94.44% and 98.42%, respectively. Combining the previous analysis of energy input and land requirement for an algal biomass raceway and mass balance of energy production and utilization, integrating the energy production (anaerobic digestion) and energy utilization (dehydration of digested sludge and power requirement of raceway) provides a great potential for a swine wastewater treatment in the tropics. HAZARDOUS SUBSTANCES IN WASTE WATER,
Rijksinstituut voor Zuivering van Afvalwater, Lelystad (Netherlands).
A. B. van Luin, and W. van Starkenburg.
Water Science and Technology, Vol. 17, No. 6/7, p 843-853, 1985. 12 Tab, 8 Ref.

Descriptors: *Wastewater, *Effluent, *Sludge, *Hazardous substances, Hydrocarbons, Industrial wastewater, Municipal wastewater, Volatile compounds, Chlorinated hydrocarbons, Aromatic compounds, Water pollution sources, Wastewater treatment.

The influent, effluent and sludge of six municipal wastewater treatment plants and wastewater from 59 industries were sampled and analyzed for hazardous substances. Volatile chlorinated hydrocarbons in sewage seem to originate mostly from industrial emissions. The amount of the emissions can fluctuate very strongly especially for dichloromethane and 1,2-dichloroethane. Chlorophenols, hexachlorocyclohexane, polychlorinated biphenyls and polycyclic aromatic hydrocarbons are always present at a low basic level in municipal wastewater and in many industrial wastewater streams. In addition to point sources there are also diffuse sources like deposition from the air and road traffic which are responsible for extra pollution of sewage. Volatile chlorinated hydrocarbons in sewage originate mainly from industrial discharges. Chlorophenols, hexachlorocyclohexane, polychlorinated biphenyls and polycyclic aromatic hydrocarbons appear to be present at a low and constant background in municipal sewage and in mainly industrial waste waters. The removal in the municipal treatment plants amounts to: volatile chlorinated hydrocarbons 50-90%; hexachlorobenzene 95%; hexachlorocyclophexanes 40-65%; chlorophenols 20-40%; PCB about 90%; PAH 85-95%. STABILIZATION OF ORGANIC CARBON AND NITROGEN IN CONSOLIDATING BENTHAL DEPOSITS,
Arizona Univ., Tucson. Dept. of Civil Engineering and Engineering Mechanics.
C. W. Bryant, Jr, and L. G. Rich.
Water Science and Technology, Vol. 17, No. 6/7, p 929-940, 1985. 5 Fig, 4 Tab, 27 Ref.

Descriptors: *Organic carbon, *Nitrogen, *Stabilization, *Benthal deposits, Mathematical models, Simulation, Biodegradation, Activated sludge, Volatile compounds, Organic loading, Wastewater lagoons.

The objective of this research was to develop and validate a predictive model of the benthal stabilization of organic carbon and nitrogen in deposits of waste activated sludge solids formed at the bottom of an aerated water column, under conditions of continual deposition. A benthal model was developed from a one-dimensional, generalized transport equation and a set of first-order biological reactions. For model verification, depth profiles of the major interstitial carbon and nitrogen components were measured from a set of deposits formed in the laboratory at 20 C and a controlled loading rate. The observed sequence of volatile acid utilization in each benthal deposits was that which would be predicted by the Gibbs free energies of the individual degradation reactions and would be controlled by the reduction in interstitial hydrogen partial pressure with time. Biodegradable solids were solubilized rapidly during the first three weeks of benthal retention, but subsequent solubilization occurred much more slowly. The benthal simulation effectively predicted the dynamics of consolidating, organic deposits. Simulation of organic loading rates up to 250 g biodegradable volatile suspended solids/(sq m day) indicated that the stabilization capacity of benthal deposits was far above average the range of organic loading rates currently used in lagoon design. A disinfection study was carried out wi natural bacterial population of a secondary wastewater effluent in a continuous flow employing different sizes of ozone bubbles termine their effects on solubility of ozo utilization and inactivation of microorganism bubble sizes were varied by changing the po of the diffusers and ozone flow rates throu ozone contactor. Natural bacterial popu (standard plate counts) present in the sec wastewater effluent was enumerated befo after ozonation. The concentration of ozone aqueous phase increases with a decrease in t of the ozone bubble for a given gas flow provided the ozone concentration remains co in the gas phase. The amount of ozone utili wastewater decreases proportionally with t of the ozone bubbles for the same gas flow ra for the same level of disinfection. For a giv flow rate and ozone residual, the degree of vation of microorganisms increases as the ozone bubbles decreases. (Moore-IVI)

On the basis of original and reference data the possibilities for the use of green and blue-green algae in waste water purification in the Bulgarian climatic, demographic and economic conditions are pointed out and their economic effectivity is evaluated. The construction of aerobic algal oxidative pools either followed by, or not followed by, fish pools is recommended. Both should not be considered as water cleaning devices, but rather as protein recycling devices. For the time being, the construction of intensive algal ponds is not recommended. (Author's abstract)

FACTORS INFLUENCING THE OZONE INACTIVATION OF ENTERIC VIRUSES IN EFFLUENT,
Stanford Univ., CA. Dept. of Medical Microbiology.
M. S. Harakeh, and M. Butler.
Ozone: Science and Engineering, Vol. 6, No. 4, p 235-243, 1984. 9 Fig, 25 Ref.

Descriptors: *Ozonation, *Wastewater treatment, *Viruses, *Enteroviruses, *Disinfection, Water chemistry, Water treatment, Ozone, Ultrasonic treatment, Hydrogen ion concentration, Bicarbonate, Sodium bicarbonate, Hydroxide, Microorganisms.

Studies on ozonation of effluent for inactivation of viruses are limited and little is known about the range of conditions which influence the efficacy of ozone; the published work has been restricted to only a few enteroviruses. In experiments with the enteroviruses, polio type 1 (LSc 2ab), coxsackie B5 and echo 1, human rotavirus, simian rotavirus SA11, and f2 coliphage, inactivation kinetics with continuously applied ozone were approximately exponential with respect to time and concentration. The most resistant of the tested viruses was human rotavirus and the most sensitive was f2 coliphage. The disinfectant was most reactive at low pH. Viral sensitivity was increased ten-fold in the presence of 0.5M sodium bicarbonate which supports the hypothesis that it was molecular O3 that was the most active molecule and not the OH radical. Neither temperature, the presence of added peptone nor suspended solids greatly influenced inactivation, but ultrasonic treatment did, whether applied before or during ozonation. It has been postulated that when ozone hydrolyzes in water, about half of it will be converted to OH radicals, the most reactive oxidant known, with the rate of the hydrolysis dependent on the concentration of ozone, the pH, and the concentration of carbonate and bicarbonate ions. Hydrolysis is accelerated by raising the pH since the formation of the OH radical is favored at alkaline pH values but is inhibited by carbonate/bicarbonate which scavenge the radical in some way which is yet to be fully elucidated. The mechanism of inactivation by ozone is little understood; whether or not all viruses would be inactivated in a similar way remains to be determined, but it is very likely that even amongst the robust enteric viruses differences would be observed, although in practice these may not be relevant. HIGH TEMPERATURE TREATMENT OF TRINITROTOLUENE (TNT) AND CYCLOTRIMETHYLENE-TRINITRAMINE (RDX) WITH OZONE AND ULTRASOUND,
Arizona Univ., Tucson. Dept. of Civil Engineering and Engineering Mechanics.
R. A. Sierka.
Ozone: Science and Engineering, Vol. 6, No. 4, p 275-290, 1984. 2 Fig, 8 Tab, 14 Ref.

Descriptors: *Trinitrotoluene, *Wastewater treatment, *Water temperature, *Ozone, *Ultrasound, *Cyclotrimethylene-Trinitramine, Water treatment, Munitions industry, Industrial wastewater.

Treatment of synthetically prepared aqueous solutions of trinitrotoluene (TNT) and cyclotrimethylene-trinitramine (RDX) in the weight ratio 70%/30%, representing a typical munitions wastewater, was researched with a combination of ozonation and ultrasound. A parametric study investigated the relationship among the variables: (1) initial solution pH (5.84 to 10.0); (2) ultrasound power level (5 to 50 watts at 852.0 to 863.0 kHz); (3) ultrasound frequency level (60.6 to 1,007.0 kHz); (4) solution concentration (70/30 mg/l TNT/RDX solutions volumetrically diluted with distilled water in the ratios 1/0, 1/3); (5) reaction temperature (25 to 59 C). Removal rates of both TNT and TOC increased directly with increases in reaction temperature and initial solution pH. Likewise, increased sound power level produced enhanced system kinetic responses; however, these were attributed to reaction mass temperature increases. Ultrasound was found to inhibit reaction kinetics at high temperatures and pH because it promoted radical-radical extinguishment reaction. (Author's abstract)

APPLICATION OF ACUTE BIOASSAYS IN EVALUATING THE TREATMENT OF COAL LIQUEFACTION WASTEWATERS,
Department of Energy, Pittsburgh, PA. Pittsburgh Energy Technology Center.
T. J. Feeley, III, and C. J. Drummond.
Bulletin of Environmental Contamination and Toxicology, Vol. 35, p 249-257, August, 1985. 2 Fig, 2 Tab, 13 Ref.

Descriptors: *Bioassays, *Toxicity, *Coal liquefaction wastewater, *Wastewater treatment, Evaluation, Gas stripping, Ammonia, Biochemical oxygen demand, Solvent extract, Toxicity, Oxidation.

Acute bioassays were performed on untreated coal liquefaction process wastewater and the wastewater following a series of treatment steps to determine the applicability of acute toxicity tests in evaluating the effectiveness of an integrated wastewater treatment strategy and selected treatment unit operations in reducing the contaminants present in the wastewater. The first step of the integrated treatment train, dissolved gas stripping, was responsible for a significant reduction in the total ammonia present in the wastewater. The largest reductions in acute toxicity were recorded after solvent extraction of the wastewater and after biochemical oxidation. The overall decrease in acute toxicity was due to significant reductions in both the inorganic and the organic contaminants present in the untreated wastewater, although the organics, specifically phenols, may play a more dominant role. Dissolved gas stripping and wet air oxidation were each performed on the untreated wastewater. Dissolved gas stripping removed the bulk of the total ammonia and sulfide from the wastewater but had little impact on the organic components and resulted in a 48 hr EC50 of only 0.12%. Wet air oxidation, on the other hand, appreciably reduced phenols, TOC, and BOD. The 48-hr EC50 of the wet air oxidized effluent was only 0.34% and probably reflects the high total ammonia remaining in the wastewater. The relatively small reductions in acute toxicity recorded after either of these two unit operations emphasize the importance of an integrated treatment program that removes both the inorganic and the organic contaminants from the wastewater. 5E. Ultimate Disposal Of Wastes

MULTI-OBJECTIVE DECISION-MAKING IN WASTE DISPOSAL PLANNING,
Oak Ridge National Lab., TN.
R. D. Perlack, and C. E. Willis.
Journal of Environmental Engineering, Vol. 111, No. 3, p 373-385, June, 1985. 1 Fig, 2 Tab, 17 Ref, 1 Append.

Descriptors: *Decision making, *Planning, *Sludge disposal, Waste disposal, Incineration, Land disposal, Ocean dumping, Economic aspects, Environmental effects, Cluster analysis, Multi-objective planning.

Ocean disposal is the present mode of disposal of the Metropolitan Boston (Massachusetts) sewage sludge; incineration and land application are alternatives being considered. A multiple objective programming model of the Boston sludge disposal problem was formulated in which the objectives of net economic benefits, environmental impact, and variability of impacts were included. A generating technique is used to solve for the noninferior solutions and cluster analysis is applied to reduce redundancy among generated solutions. The end result of this analysis is an array of possible solutions to the disposal problem, none of which are unambiguously superior. On the basis of cost, the ocean disposal solutions are clearly superior, while the solutions involving multiple disposal modes are the most expensive. Agricultural land application is somewhere in between. The reverse is true for the environmental impact objective, with land application again occupying the middle ground. An array of results such as this is likely to be more valuable to decision-makers than requiring them to articulate their conception of the social preference function (in advance of knowledge of the complete solution space), and then presenting them with a single optimum solution. This technique provides the maximum quantity of information to the decision-maker. (Moore-IVI)

CONTROLLING METAL UPTAKE FROM HEAT-TREATED SLUDGE APPLIED TO GRASSLANDS,
Port Elizabeth City Engineer's Dept. (South Africa).
J. W. Vail, and D. G. Devey.
Water Science and Technology, Vol. 17, No. 4/5, p 599-610, 1985. 6 Tab, 23 Ref.

Descriptors: *Metals, *Grasslands, *Sludge disposal, *Land disposal, Zinc, Nickel, Lead, Chromium, Pastures, Turf, South Africa, Standards.

A Zimpro heat-treated sewage sludge containing high levels of zinc, nickel, lead and chromium was successfully used to establish high-grade pastures and turf on two different coastal soils in South Africa, using guidelines and developed in the United Kingdom to control the rate of application. The properties and composition of the sludge and soils are described and levels of metals in the grass are reported. The rates of application suggested by the guidelines were effective in preventing excessive metal uptake. The results obtained are discussed in relation to tentative guidelines for controlling sewage sludge applications to land in South Africa. (Author's abstract)

To improve the morphology of the sandy soils of Apsheron, Azerbaijan S.S.R., for the cultivation of vegetables, experimental studies with increasing doses of water pipe sludge applied per hectare of ground were carried out. The control soil samples featured a loose structure due to the presence of coarse mineral grains with rare carbonized plant inclusions. The mineral constituent was basically of calcitric and feldspar nature and had no colloidal membranes. Carbonates and organic substances were the basic binding constituent and the soil was lacking microaggregation. The sludge used in this study was dark grey, featured a tight structure with fine grain calcite and rare single pores. Application of 5, 10, and 30 T/Ha improved the microstructure of the sandy soil with increasing dosage of sludge generating ground plasma and soil aggregation. (Erdelyi-IVI)

The influence of humic acids on the adsorption of the pesticide 2,4-D (2,4-dichlorophenoxyacetic acid, sodium salt) by aluminum oxide in the treatment of drinking water was investigated. Organic and inorganic anions are adsorbed by aluminum oxide; among the latter in particular, sulfate ions and phosphate ions. The adsorption rate rises with declining pH values. The dissociation constant of 2,4-D (free acid) is 0.0023 and is of the general order of the dissociation constant of salicylic acid. (Moore-IVI)

EXPRESSION FOR DRINKING WATER SUPPLY STANDARDS,
Roorkee Univ. (India). Dept. of Civil Engineering.
D. S. Bhargave.
Journal of Environmental Engineering, Vol. 111, No. 3, p 304-316, June, 1985. 5 Fig, 2 Tab, 6 Ref, 1 Append.

Descriptors: *Drinking water, *Water quality standards, Water quality index, Model studies.

Various authorities and regulating agencies have set standards for deciding the suitability of a water for drinking purposes. These standards prescribe the permissible concentrations of quality variables. When some variables exceed the permissible levels, a decision for permitting further use of the water supply has to be based on the importance of those variables with exceeded concentrations. It is proposed that standards for a drinking water supply should be set through a single number representing the integrated effect of all the variables, due regard to the importance of each Such an integrated water quality index would help in decision making. Models and have been presented to evolve a WQI for water supplies. It is suggested that water WQI lower than 90 should not be permitt acceptable quality therefore, should be in range of the WQI. Descriptors: *Maintenance, *Reservoirs, *Bacteria, *Detergents, Reservoir operation, Drinking water.

As a rule drinking water reservoirs are cleaned in one year intervals for which purpose special detergents are frequently used. After such cleaning an increase of colony counts has been observed again and again. Up to now however it has not become clear whether the detergents have an influence on this result. In a laboratory examination 5 detergents were tested by cleaning cement mortar and high-grade steel plates. After the purification of the cement mortar plates 4 of the 5 materials examined showed an increase of colony counts and of TOC in the water. Examination of the high-grade steel plates did not show either an increase of colony counts or a charge of TOC. (Author's abstract)

DISINFECTION OF DRINKING WATER RICH IN BROMIDE WITH CHLORINE AND CHLORINE DIOXIDE, WHILE MINIMIZING THE FORMATION OF UNDESIRABLE BY-PRODUCTS,
Hadassah Medical School, Jerusalem (Israel). Environmental Health Lab.
C. Rav-Acha, A. Serri, E. G. Choshen, and B. Limoni.
Water Science and Technology, Vol. 17, No. 4/5, p 611-621, 1985. 4 Fig, 4 Tab, 21 Ref.

Descriptors: *Drinking water, *Disinfection, *Bromides, *Chlorination, *Chlorine dioxide, Trihalomethanes, Chlorite, Halogenated hydrocarbons, Chemical reactions, Water treatment.

Although chlorine dioxide does not form trihalomethanes (THM) and produces very few non-volatile haloorganic materials in drinking water, intensive investigations bearing on the formation of chlorite by ClO2 disinfection reveal that the rate of chlorite formation reflects the rate of ClO2 consumption and as long as the amount of ClO2 applied is behind its demand, about 60% of the chlorine dioxide consumed is converted into chlorite. Mixtures of Cl2 and ClO2, which may successfully reduce the formation of haloorganic compounds, as well as of chlorite in the absence of bromide, fail to do this where water rich in bromide is concerned. As a result of bromide oxidation by chlorine, bromine is formed, which in turn reacts more intensively with organics than does chlorine and thus favors the formation of THM and other halogenated organic materials. This problem can, however, be circumvented if ClO2 is allowed to react in water with the organic precursors before chlorine is introduced. A pre-treatment with 1 ppm of ClO2 two hours before the application of 2 ppm Cl2, was found to reduce the formation of THM by 60% relative to its formation by chlorine alone, and the chlorite is reduced in this case by up to 90% relative to its formation by chlorine dioxide alone. This is of particular importance since it can solve some of the major problems bearing on the impact of disinfection upon the formation of undesirable by-products. (Author's abstract)

OCCURRENCE OF VIRUSES IN TREATED DRINKING WATER IN THE UNITED STATES,
Health Effects Research Lab., Cincinnati, OH.
E. W. Akin.
Water Science and Technology, Vol. 17, No. 4/5, p 689-700, 1985. 3 Tab, 30 Ref.

Descriptors: *Viruses, *Drinking water, Water treatment, Surface waters, Public health, Enteroviruses.

Health concerns regarding waterborne transmission of enteric viruses began to develop around 1940 in the U.S. with the isolation of poliovirus from human feces and sewage. The implication of these isolations for the transmission of viral disease through contaminated drinking water stimulated research on methodology for virus detection, recovery and assessment from water. Although virus methods research is still an important area of study, relatively sensitive procedures became available during the past decade for recovering many enteric virus types from large-volume samples of drinking water. Controversy surrounded many of the early reported isolations of viruses from treated drinking water using these procedures due to the suspicion of laboratory contamination. The occurrence of viruses in drinking water treated by currently accepted procedures has still not been proven by the U.S. experience although the likelihood may be gaining support. However, a virus survey of 54 water supplies and extensive studies of two water systems by the U.S. Environmental Protection Agency did not demonstrate viral contamination of treated water derived from surface sources. OZONE ENHANCED BIOLOGICAL ACTIVATED CARBON FILTRATION AND ITS EFFECT ON ORGANIC MATTER REMOVAL, AND IN PARTICULAR ON AOC REDUCTION,
Studiesyndicaat voor Water, Antwerp (Belgium).
J. G. Janssens, J. Meheus, and J. Dirickx.
Water Science and Technology, Vol. 17, No. 6/7, p 1055-1068, 1985. 9 Fig, 7 Tab, 33 Ref.

Descriptors: *Activated carbon, *Filtration, *Ozonation, *Organic matter, Water treatment, Biodegradation, Organic compounds, Filtration, Biological treatment.

Ozonation of organic compounds in water usually produces oxygenated organic byproducts that are more readily biodegradable. Ozonation prior to granular activated carbon (GAC) filtration is evaluated in relation to organic matter removal, and in particular to AOC (assimilable organic carbon) reduction. Ozonation prior to GAC filtration resulted in a final water quality with generally a lower organic matter concentration. In terms of total organic carbon (TOC) removal, experimental results on pilot plant scale showed an increase of filter service time with about 60% to 65%. A dosage higher than 2 mg ozone/l had no additional effect. The extent to which this increase of service time was predominantly due to enhanced biological activity or to long term cumulative slow adsorption is not clear. An indicative economic analysis showed that the costs, as a result of ozonation, could not be covered by the cost-savings in reactivation of activated carbon. Ozonation caused a very significant increase of AOC. This was a function of the applied ozone dosage. Under equivalent conditions, GAC filtration of non-ozonated water gave the lowest AOC values in its effluent. First experimental results suggested a relation between ozonation and an early 'breakthrough' of AOC with GAC filters fed with ozonated water. If an AOC limit value is applied as a criterion for filter operating time, ozonation prior to GAC filtration would result in a significant shortening of the filter service time. (Moore-IVI)

OZONATION OF NON-IONIC SURFACTANTS IN AQUEOUS SOLUTIONS,
Technion - Israel Inst. of Tech., Haifa. Environmental and Water Resources Engineering.
N. Narkis, B. Ben-David, and M. S. Rotel.
Water Science and Technology, Vol. 17, No. 6/7,

p 1069-1080, 1985. 14 Fig, 2 Tab, 24 Ref.

Descriptors: *Surfactants, *Ozonation, Wastewater treatment, Water treatment, Organic carbon, Polyethylene glycol, Oxidation, Biodegradation.

The effect of ozone on dilute aqueous solutions of a series of non-ionic surfactants of nonyl phenol ethoxylates, with n = 4 to 30 ethylene oxide groups, dinonyl phenol ethoxylate and a polyethylene glycol were investigated. Assuming ozone concentration in solution to remain constant throughout the ozonation, the experiments showed first-order reactions with respect to surfactant concentration, as measured by the Wickbold method, and also with respect to COD and TOC. A linear relationship was established between the first-order reaction rate constants, and between n, the average number of ethylene oxide groups in the ethoxylate chain of the nonyl-phenol ethoxylate series. The oxidation mechanism by ozone of non-ionic surfactant molecules is explained as mainly polyethoxylate chain's cleavage into shorter polyethylene glycols and to a smaller extent oxidation of the aromatic ring. High ozone doses do not convert the non-ionic surfactant completely to CO2 and H2O but smaller doses are sufficient to enhance biodegradation. (Author's abstract)

MODELLING OF THE COAGULATION-ADSORPTION PROCESS IN TREATMENT SYSTEMS,
Wroclaw Technical Univ. (Poland). Inst. of Environment Protection Engineering.
A. M. Dziubek, and A. L. Kowal.
Water Science and Technology, Vol. 17, No. 6/7, p 1113-1120, 1985. 2 Fig, 5 Ref.

Descriptors: *Mathematical models, *Coagulation, *Adsorption, Water treatment, Wastewater treatment, Organic matter, Chemical treatment.

Removal of organics in water or wastewater treatment systems is often described mathematically in the form of Langmuir and Freundlich adsorption isotherms. Using these equations, it is convenient to model, e.g., the removal of organic matter in the adsorption process on an activated carbon bed. In chemical treatment processes, organic substances are frequently removed from the water or wastewater under treatment via an adsorption on the precipitation products. In this paper presented is a generalized model of the equation of a multilayer adsorption isotherm, which describes total organic carbon removal from a solution during chemical treatment in an alkaline medium. The model also includes the nonremovable concentration of organics. (Author's abstract)

Descriptors: *Chromium, *Drinking water, *Water treatment, Water pollution sources, Air pollution, Metal-finishing industry, Groundwater pollution, Iron sulfate, Filtration, Automation, Meulan district, France.

A series of tests were performed with a view to solving the problem of chromium pollution in the Meulan district near Paris (France) due to the proximity of long-established metal-working plants. It was found that the accumulated pollution not only originated from the groundwater source but also from atmospheric contamination through fall-out from smoke and fumes issuing from local metal-works' stacks. Among the interesting features of this paper is the fact that, since the profound penetration by the pollutant affects potable feedstock, chromium removal studies have been made on potable water for the first time on record. Several methods are reviewed, among which the only economically feasible one appears to be the reduction of hexavalent chromium by a sufficient quantity of iron sulfate, the problem attached to iron-sulfate overdose being solved by the application of high-rate filtration on very fine sand. This arrests the fine precipitates and reduces the residual ferrous-iron by catalysis. Reliability of the treatment is ensured by a system of continuous metering that automatically controls reagent dosing. (Author's abstract)

Due to the high turbidity of the waters of the Kura River a special method of their treatment has been outlined in Baku. To intensify the purification process the application of bentonites from various deposits of Azerbaijhan along with coagulants and a special flocculating agent has been recommended, while substituting the quartzite sand with natural deposits as filtrating material. The suspensions of bentonites from Agburun coagulate in the presendece of Ca(2+), Mg(2+), Na(+), K(+) cations of natural waters. Coagulation occurs within a wide range of pH, water hardness, salinity, and turbidity. The use of bentonites decreases by 1.5 or 2 times the consumption of coagulating agents. When used in combination with flocculating agents the need for aluminum sulfate decreases to zero while increasing the yield of the water purification plants and maintaining a high quality water supply. The optimal doses of Agburun bentonites range between 10-200 mg/l. Application of aluminum sulfate or flocculating agents in addition to bentonite permits a decrease of the latter by 30-50%. To develop a toxicologic profile of these substances for the recommendation of their use in the purification of natural waters for water supply acute, subacute and chronic toxicity experiments were carried out on rats. The physiological parameters under investigation including a swim test, a erythrocyte and leukocyte count and the determination of blood catalase and peroxidase. The acute experiment indicated that bentonite was not toxic in that its maximum tolerable concentration for the experimental animals was of 66 g/kg. No alterations in blood composition were seen and the swim test was no different from the control animals. The subacute experiment lasting 2 months with bentonite administered orally in 1.5, 7.5, and 15.0 mg/kg doses revealed no alterations in the explored functions of the rats. The chronic experiment (6 Mo) with animals treated with similar dose of bentonite showed no changes in the above parameters. Bentonite from Agburun was then officially approved as a substance to be used in water purification for water supply. (Erdelyi-IVI)

Ozone: Science and Engineering, Vol. 6, No. 4, p 245-260, 1984. 17 Fig, 1 Tab, 17 Ref.

Descriptors: *Water treatment, *Ozonation, *Biological activated carbon, *Sand filtration, *Granular activated carbon, *China (Peoples Republic), *Harbin, *Heilongjiang, Activated carbon, Filtration, Turbidity, Color, Odor, Iron, Manganese, Organic substances, Chemical oxygen demand, Biological oxygen demand, Chromatograms, Ammonium, Nitrates, Water pollution.

In order to determine effective processes for purifying polluted source waters in Harbin City (Heilongjiang Province, China) various processes consisting of ozonation, sand filtration, and/or GAC filtration and adsorption, i.e., ozonation ('O3' Process), ozonation/sand filtration ('O3 + SF' Process), ozonation/biological activated carbon ('O3 + BAC' Process), ozonation/sand filtration/biological activated carbon ('O3 + SF + BAC' Proces), and granular activated carbon ('GAC' Process) were tested in an 8 cu m/d capacity pilot plant. In addition, a small plant of 500 L/d capacity was used to conduct comparative studies between the two processes 'GAC' and 'O3 + BAC', as well as two types of carbon. Of the processes tested, both the 'O3 + BAC' and 'O3 + SF + BAC' processes are most effective in removing various pollutants, including turbidity, color, odor, iron, manganese, organic substances measured as COD, BOC, chromatograms, and ammonium, nitrite, and nitrate ions. Specific efficiencies and mechanisms for removing such pollutants are described and discussed in detail. Based on the results of this study, two treatment flow sheets have been put forward for purifying polluted surface source water and polluted groundwater sources, respectively. (Author's abstract)

PRELIMINARY STUDY OF THE EFFICIENCY AND MECHANISM OF THM REMOVAL IN THE OZONATION AND BAC PROCESS,
Harbin Civil Engineering Inst. (China). Water Pollution Control Lab.
B. Wang, J. Yin, J. Tian, Q. Fan, and R. Liu.
Ozone: Science and Engineering, Vol. 6, No. 4, p 261-273, 1984. 8 Fig, 1 Tab, 16 Ref.

Descriptors: *Trihalomethanes, *Halogenated hydrocarbons, *Ozonation, *Water treatment, *Activated carbon, Chloroform, Water pollution sources, Chemical reactions, Anaerobic conditions, Adsorption.

A preliminary study on removing THMs from chlorinated water by ozonation ('O3' process) and granular activated carbon bed filtration and adsorption ('AC' process) was carried out. The chloroform content in chlorinated water was reduced to some extent by ozonation at low dosages, but then it increased steeply with time, and finally reached much higher than the original values. The GAC beds in both the 'AC' and 'O3 + AC' processes were found to be effective in removing chloroform by adsorption during their early operating period, corresponding to 4,000 - 5,000 bed volumes throughput, or one month duration for carbon X-11 and carbon ZJ-15 beds in the 'AC' process. With preozonation, i.e., the 'O3 + AC' process, the operating period with positive chloroform removal efficiencies was tripled. Nevertheless, the chloroform content in effluents from the GAC bed in both processes increased with operating time and throughput, and finally became much higher than the level in the influents. The phenomenon presumably was due to three mechanisms occurring in the carbon beds: 1) the biodegradation of complex chlorinated compounds into THMs: 2) the anaerobic digestion products can react with free chlorine in water to form THMs; 3) the desorption of THMs adsorbed on the carbon surfaces. In order to prevent the treated water from producing high concentrations of THMs, chlorination should be avoided before either the 'AC' or the 'O3 + AC' process. Home use carbon filters also are recommended to be used carefully and reasonably, for they can increase THM concentrations in effluents to levels much higher than those in the influents after a certain time of operation. EFFECTS OF PH ON REMOVING LOW-LEVEL CHROMIUM CONTAMINATION IN GROUNDWATER,
Tennessee Technological Univ., Cookeville.
J. T. Mason, III, and C.-Y. P. Liau.
Journal of the Tennessee Academy of Science, Vol. 60, No. 3, p 77-79, July, 1985. 3 Fig, 2 Tab, 4 Ref.

Descriptors: *Chromium, *Hydrogen ion concentration, *Adsorption, Water treatment, Groundwater pollution, Adsorbents, Acidity, Flow rate.

Research on removal of low-level chromium contamination from samples of groundwater, along with included impurities, is described. A series of tests varying adsorbent amount, flow rate, and pH was conducted. In all cases the resin, Duolite ES-392, performed better than either of the carbons, Witco Witcarbon 950 or GECA Carborundum GAC 30, as adsorbents. The minimum adsorbent quantity (6 gm) and the medium flow rate (4.07635 ml/min) produced satisfactory chromium removal from pH 5 to 7 with the optimum pH somewhere closer to pH 5. The amount of chromium adsorbed increased from lower pH to near 5.6 and then decreaed rapidly with increasing pH values in the groundwater. The effects of flow rate demonstrate that velocity is a significant factor in treating to under 0.05 mg/l chromium. (Baker-IVI)

5G. Water Quality Control

RESTORATION OF A SMALL LAKE BY COMBINED MECHANICAL AND BIOLOGICAL METHODS,
Bayerisches Landesamt fuer Wasserwirtschaft, Munich (Germany, F.R.).
V. Kucklentz.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2314-2317, 1985. 1 Fig, 2 Ref.

Descriptors: *Biological control, *Lake restoration, *Unterfoehringer See, *Germany (Federal Republic), Rehabilitation, Macrophytes, Fish, Ecological effects, Chara, Chlorophyta, Recreation, Phytoplankton, Carp, Microcystis, Cyanophyta, Cyclotella, Asterionella.

Removal of sludge, mechanical removal of macrophytes, and introduction of fish were tried in a series of attempts to improve clarity and prevent overgrowth of a small (5.5 hectare) swimming lake, the Unterfoehringer See, West Germany. In 1972, water quality was bad, and Secchi disk transparency had decreased by 0.8 m. In 1975/76, sludge was dredged from the lake, but in summer 1977, Chara hispida covered nearly the entire lake, making fishing and swimming impossible. In autumn 1977, the lake was drained and Chara mechanically removed. To prevent redevelopment of the Chara, 1,000 grass-carp (Ctenopharyngdon idealla Val.) were introduced to the lake in April 1978. Fish were observed feeding on the filamentous algae and on the young leaf buds of Chara but during summer mass development of phytoplankton occurred. In August and September 1979, massive Cyclotella and Asterionella appeared, and in October of that year the lake was drained again. Total grass carp biomass had increased from 190 kg to at least 622 kg since introduction. Grass-carp (totalling 75 kg) were restocked, and in May 1981 silver carp (150, mean weight 190 g) were introduced. In April 1983 two specimens of each species of fish were obtained; the grass carp weighed 2,200 and 2,650 g and the silver carp weighed 700 g and 950 g. Plankton blooms have continued, and since 1981 blue-green algae have increased significantly. Microcystis has appeared recently for the first time. (Rochester-IVI)

WATER QUALITY CONTROL IN IMPOUNDMENTS,
Institut Hygieny a Epidemiologie, Prague (Czechoslovakia).

J. Chalupa, L. Fiala, J. Popovsky, V. Sladecek, and P. Vasata.
Acta Hydrochimica et Hydrobiologica, Vol. 13, No. 1, p 3-16, 1985. 3 Fig, 1 Tab, 39 Ref.

Descriptors: *Water quality control, *Reservoirs, Water pollution sources, Eutrophication, Multipurpose reservoirs, Sediments, Aquaculture, Network design, Sampling, Monitoring, Czechoslovakia.

This report on a seminar of the Water Research Institute in Prague deals with the methodological aspects of the measurement and evaluation of data for the water quality in impoundments in the CSSR mainly with respect to: the assessment of external causes, especially of anthropogenic influences in the catchment area, on the water quality (eutrophication, humic substances, trace elements), of the multi-purpose utilization of impoundments, the classification and development of the water quality in impoundments, the intensified utilization of impoundments as well as the influences of sediments and the effect of piscicultural measures on the water quality. The paper is subdivided into the following chapters: system of measurement network and analysis, stratification number of samples, number of the criteria to be investigated, extreme periods of discharge, multi-purpose utilization of impoundments, eutrophication, fish stocks. GROUNDWATER POLLUTION HAZARD IN THE CAPE FLATS,
National Inst. for Water Research, Bellville (South Africa). Cape Regional Lab.
G. Tredoux.
Water Pollution Control, Vol. 83, No. 4, p 473-483, 1984. 11 Fig, 1 Tab, 10 Ref.

Descriptors: *Water quality control, *Monitoring, *Groundwater pollution, *Cape Flats, *South Africa, Water resources development, Groundwater, Water supply, Waste disposal.

The results of water quality monitoring in the Cape Flats are given and the implication of groundwater pollution are discussed, particularly in view of the proposed exploitation of the aquifer as a water source. The quality of the natural groundwater stored in the Cape Flats aquifer complies with the standards for domestic supplies, and the aquifer therefore has potential as a water supply source for Cape Town. The Cape Flats aquifer is unconfined, therefore it is vulnerable to pollution. In many places the groundwater level is close to the surface, which adds to the aquifer's susceptibility to pollution. Hazardous activities should be kept out of the area if the water source is to be protected. Pollution of the aquifer by leachates from landfills and sewage effluents has been proved by water quality monitoring. Waste disposal and sanitary landfilling should always be carried out with full precaution, even if pollution is not expected. The thickness of the unsaturated zone below a sanitary landfill is possibly the most important factor determining the groundwater pollution potential of the fill. Serious interaction takes place when the groundwater is in contact with the waste. The disposal of treated sewage effluent from an activated-sludge plant into the aquifer is not necessarily deleterious. Leachate from sludge drying beds should not be allowed to reach the aquifer. ESTIMATION OF THE LOADS OF SOME LIST I AND II SUBSTANCES TO UNITED KINGDOM TIDAL WATERS - A COMPARISON WITH PREVIOUS ESTIMATES,
Water Research Centre, Stevenage (England).
A. R. O'Donnell, and G. Mance.
Water Pollution Control, Vol. 83, No. 4, p 554-561, 1984. 1 Fig, 8 Tab, 7 Ref.

Descriptors: *Water quality control, *United Kingdom, *Pollution load, Wastewater discharge, Water pollution prevention, Rivers, Flow, Estimating, Coastal waters.

Current estimates of the loads of dangerous substances discharged to coastal waters in the United Kingdom are based on a comprehensive database including information from all significant land-based sources. The results are generally lower than previous estimates based on less comprehensive data. The loads discharged by rivers represent the largest percentage contribution to the overall inputs of these substances to coastal waters. Reduction of the uncertainty associated with quality data from sites reporting many results below the limit of detection, in combination with the utilization of flow data based on small sampling intervals, has resulted in a more realistic assessment of the loads contributed by rivers. For sewage discharges lacking quality data, estimated concentrations have been substituted. In general, the effluents, with measured water quality, serve large populations and the application of their quality data to other, smaller, discharges may bias these sewage load estimates. The loads from industrial discharges presented in this survey are undoubtedly overestimates, as a proportion of the loads have been evaluated using consented flows and concentrations. More realistic estimates of the loads of dangerous substances discharged to coastal waters can only be obtained from improved measurements of flow and water quality. (Baker-IVI)

RESTORATION OF LAKE VELUWE, THE NETHERLANDS, BY REDUCTION OF PHOSPHORUS LOADING AND FLUSHING,
Rijksinstituut voor Zuivering van Afvalwater, Lelystad (Netherlands).
S. H. Hosper.
Water Science and Technology, Vol. 17, No. 4/5, p 757-768, 1985. 8 Fig, 5 Tab, 6 Ref.

Descriptors: *Lake restoration, *Phosphorus, *Lake Veluwe, *Netherlands, *Flushing, Eutrophication, Oscillatoria, Algae, Species diversity, Chlorophyll a, Biomass, Transparency.

In the shallow and hypertrophic Lake Veluwe (Netherlands) the cycling of phosphorus between water and sediments was mainly determined by a continuous bloom of the blue-green alga Oscillatoria agardhii. For the restoring of water quality it was considered necessary to reduce the external P-loading as well as to suppress the release of phosphorus from the sediments. The P-loading of the lake decreased from approximately 3 to 1 g P/sq m a year in 1979. Additionally the lake has been flushed during winter periods with water low in phosphorus. Flushing was primarily aimed at interrupting the continuous algal bloom. After four winters of intensified flushing Oscillatoria still is the dominant alga but the diversity of species is increasing. In 1982 Oscillatoria disappeared for several months. The results show a sharp decline of summer values of total phosphorus from 0.40-0.60 mg/l to approximately 0.15 mg/l. In the trend of various parameters correlated with algal biomass a striking discrepancy is observed. Chlorophyll-a, ashfree-dryweight and particulate-phosphorus show a considerable and approximately similar decrease (50-60%). On the other hand the decrease of algal biomass in terms of freshweight (viz. biovolume of Oscillatoria) and reciprocal Secchi-disc values is relatively small (app ly 25%). Obviously the O. agardhii filam tain much less organic matter, chlorophyl phorus and nitrogen per unit of biovol implementation of remedial measures. Tr cy appears to be determined by nut volume of O. agardhii more than by chlo and ashfree dryweight. Intensified flushir continued for the next few years. (Aut stract)

environmental quality standards

(EQSs) for coastal waters and the difficulties of using such standards for controlling industrial discharges are discussed. Attention is focused on the common List II substances (copper, chromium, lead, nickel, zinc and arsenic) and their effects on marine life. Marine toxicity data are largely limited to relatively short exposure periods under conditions of constant temperature, salinity, and concentration of test substance. Insufficient attention has been directed to investigating the significance of such environmental factors as salinity and temperature on the toxicity of the List II heavy metals. Field studies of the environmental impact of heavy metal discharges to coastal waters are required that adequately describe the spatial and temporal variations in water quality as well as biota. In practice the available toxicity data enable an initial assessment of the EQSs. Progressive extension of regulatory controls to all tidal discharges, with the phased implementation of Part II of the Control of Pollution Act means that these tentative EQSs will be judged against the real world by their use in licensing existing discharges. Implementation of these controls will undoubtedly increase the availability of field impact assessments enabling the EQSs to be reviewed and subsequently restated with increased confidence. EEC SHELLFISH DIRECTIVE IN WALES,
University Coll. of Wales, Aberystwyth. Dept. of Botany and Microbiology.
S. N. Young, and P. Wathern.
Water Science and Technology, Vol. 17, No. 6/7, p 1199-1209, 1985. 1 Fig, 5 Tab, 13 Ref.

Descriptors: *Wales, *Shellfish, *Water quality standards, Water pollution control, International agreements, United Kingdon, Standards, Monitoring, Public health.

This paper contains details of the procedures adopted by the UK Government in implementing the EEC shellfish directive and a review of the water quality monitoring programs used by the Welsh Water Authority with respect to these provisions. Six shellfish beds have been surveyed in detail by the Authority, but only one has been designated. This is the only shellfishery which meets the standards. Raising the remainder to the required standards would involve considerable capital expenditure, mainly for sewage treatment. The UK Government has precluded such expenditure. It has claimed that any public health measures inherent in the directive are covered adequately by current UK practice. This stance is questioned in the light of a recent viral study. This paper highlights the potential problems when there is conflict between international and national water quality priorities. (Author's abstract)

COUNTY RESTORES GROUNDWATER AQUIFER,
Fresno County Public Works Dept., CA.
R. D. Welton.
Public Works, Vol. 116, No. 7, p 58-60, July, 1985. 3 Fig.

Descriptors: *Aquifers, *Groundwater pollution, *Water quality control, Water supply, Landfills, Percolation, Leakage, Water pollution sources.

The Southeast Regional Solid Waste Commission's Disposal Site is a 74 acre municipal landfill that has recently acquired statewide notoriety in California because it is suspected of degrading groundwater in its immediate vicinity. This degradation primarily involves volatile organics trichloroethylene and tetrachlorethylene. The landfill operated between 1970 and 1979 without any detected water problems. In 1979 the groundwater monitoring detected an increase in iron and manganese in two of the monitoring wells. On investigation, the landfill was found to be saturated in several areas. Three possible sources of the moisture were discovered: an agricultural irrigation pipeline was leaking; a small segment of the landfill had been completed and landscaping had been installed with a drip type irrigation system which was leaking; and the interim level grade of the landfill did not properly redirect rainfall runoff and percolation was a problem. Two treatment options, a granular carbon filtration system and an air stripping process were considered for the removal of volatile organic and inorganic contamination. Field testing of the air stripping method showed it effectively removed volatile organics by volatilization and oxidized iron and manganese. This aquifer restoration project supports the contention that groundwater restoration is expensive, even with the low cost air spraying process used. Considering the low level of contamination and the small area involved in this project, the near half million dollar expenditure thus far equals about 40 cents for every ton of buried waste in the landfill. Future continued operational and maintenance costs are expected to cause the total cost to eclipse this half-million dollar amount. When confronted with a moving plume of contamination, it may be more efficient to attack the problem with a staged construction contract immediately. Quickly pursuing a project may reduce costs overall. (Baker-IVI)

6. WATER RESOURCES PLANNING

6A. Techniques Of Planning

ORGANIC POLLUTION; MANAGEMENT OF FRESH WATERS: INPUT OF SCIENTIFIC DATA INTO POLICY FORMULATION IN THE UNITED STATES,
College of New Rochelle, NY. School of Arts and Sciences.
M. M. Holland, and J. J. Balco.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2221-2225, 1985. 1 Fig, 2 Tab, 9 Ref.

Descriptors: *Resource management, *Policy making, *Environmental impact, *Water resources development, Resources development, Administrative agencies, Decision making, Administrative decisions.

Historically, there has been a strong federal role in the management of water resources in the United States. Prior to the 1970's water resource management decisions typically considered mainly economic factors; the agencies responsible for implementing programs (eg, US Army Corps of Engineers, Bureau of Reclamation, Soil Conservation Service, and Tennessee Valley Authority) have been, and continue to be, largely civil-engineering, construction-oriented agencies. Since passage of the National Environmental Policy Act in 1969 as well as other environment protection legislation, emphasis in mangement decisions has shifted from economic benefits toward considerations of impacts of human activities on ecosystems. The institutional arrangements for water resource management decision-making in the United States are exceedingly complex, and scientific input is not necessarily the basis of policies. Two recent examples of scientific participation in the decision-making process governing management of US freshwater wetlands are: (1) the wetlands preservation program of The Nature Conservancy, a private group that acquires critically important wetland areas to ensure their preservation, and (2) a program sponsored by the US Department of Transportation Federal Highway Administration, in which scientists were asked to review a report on functional wetland assessment. A third way for scientists to have input in the decision-making process is through increasing public awareness, because Congressmen vote as their constituents tell them. In the future, three steps are necessary to increase the influence of scientists in the decision-making proc-

ess governing US fresh waters: (1) create standard methodologies for obtaining, presenting, and evaluating data; (2) develop policies that recognize that ecosystems are dynamic resources; and (3) improve communication between scientists and important groups of nonscientist, such as economists, the news media, personnel of regulatory agencies, and, especially, the average citizen. PROBLEMS IN WATER RESOURCES UTILIZATION,
Asian Inst. of Tech., Bangkok (Thailand).
I. Fude.
Indian Journal of Power and River Valley Development, Vol. 33, No. 5/6, p 175-180 and 187, May-June, 1983.

Descriptors: *Water resources development, *Planning, Conservation, Economic aspects, Soil erosion, Water demand, Water quality, Hydroelectric plants, Technology transfer, Flood control, Agriculture.

In this era of scientific proliferation, startling new discoveries and inventions are being made in an unceasing stream, but the application of modern scientific discoveries and principles in water technology lags far behind. Areas in which attention is needed include: conservation of water supply; excesses in water resources planning; screening and review of water development plans; post-implementation cost accounting; financing water resource development; the need for reservoir storage space; soil erosion; energy and power surveys; underground hydroelectric powerplants; manpower planning; research and development; dissemination and exchange of information; standardization of measurement systems; the accumulation of useful experience; daily weather reports, flood control, agricultural production; and water quality. In water resources utilization, solutions can be found through the imagination, ingenuity and industry of the people and the transfer of technology and expertise. Care must be taken in the transplant of technique and methodology without adaptation or modification to suit or meet peculiar local or national requirements. (Moore-IVI)

MECHANISATION VS. MANUAL EXECUTION OF RIVER VALLEY PROJECTS IN MAHARASHTRA,
Bhatsa Project Circle, Thane (India).
V. R. Deuskar, and M. V. Bhave.
Indian Journal of Power and River Valley Development, Vol. 33, No. 9/10, p 330-342, September-October, 1983. 4 Fig, 5 Tab.

Descriptors: *Construction, *Mechanization, *Maharashtra, *India, Planning, Dams, Canals, Water resources development, Dams, Hydroelectric plants, Irrigation projects, Water supply.

The subject of mechanization vs. manual labor in river valley construction projects has been discussed in Maharashtra for the last two or three decades. The river valley projects may be irrigation, water supply, hydropower, or multipurpose plans. There appears to be no single answer to the the problem of choosing mechanization or manual labor, which would be applicable to all situations and all times. Each case is an individual by itself and a choice has to be made by those in charge after taking into account many factors such as site conditions, time available, machinery and equipment already in hand, the need regarding providing employment, possibility of repetitive use of machinery, ready availability of labor and others. In the long run the trend is toward mechanization, and India will also be caught up in this trend. In the near future the construction industry will have to gear up for gigantic projects, and mechanization for the critical elements of these will be inescapable in order to keep on construction schedules. INCREASE OF THE EFFECTIVENESS OF USING THE HYDROPOWER RESOURCES OF THE ENISEI RIVER,
G. S. Arsev'ev.
Hydrotechnical Construction, Vol. 18, No. 10, p 461-464, October, 1984. 1 Tab, 4 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 10, p 4-6, October, 1984.

Descriptors: *Enisei River, *USSR, *Hydroelectric power, Water resources development, Economic evaluation, Efficiency, Runoff, Electrical networks, Water management, Interbasin transfers.

For hydropower stations with a different degree of regulation and located on rivers with an asynchronous runoff regime, when united into an integrated power grid, the most effective operating regime is a regime of compensating electric power regulation, as a result of which the effectiveness of using the hydropower resources and total firm output increase. The effect of asynchronous runoff and the effect of compensating regulation on the total firm output of hydrostations under combined operating conditions of existing and planned hydrostations in the lower Enisei basin (USSR) were investigated. Investigations were carried out by direct comparison of the variation of the runoff from different parts of the basin and determination of the correlations for a combined period of observations from the 1937-1938 to the 1975-1976 water management years. Calculations to establish the effect of asynchronism of the annual runoff on an increase of the total firm output of hydrostations both in the case of independent and compensating regulation were performed on the basis of using the equation of the variance of the total series composed as a result of adding individual n series. The results indicate that the onetime economic effect due to organizing and conducting interbasin compensating regulation at hydrostations in the lower Enisei basin can amount (at a cost of 176 rubles per 1 kW of installed capacity of a thermal power station and with consideration of construction of transmission lines) to about 160 million rubles. The advantage of hydro power is that the
renewable and the production of power
consume the water. The main objection a
large hydro schemes has been the high
vestment involved in the beginning and
gestation required before the benefits
reaped. In India during 1981-82 the tota

ion was about 123 TWh of which the share
o was 40.3%, thermal 56.6%, nuclear 2.4%,
sel and gas turbine 0.7%. In Uttar Pradesh
end of 1968 percentage of hydro installation
out 52% of the total capacity. The pace of
ectric development slowed down after
spite of its intrinsic merits. The most im-
factor was a lack of financial resources.
al hydro potential in Uttar Pradesh is esti-
o be 13,000 MW of which only 1,200 MW
en commissioned so far. Having used only
he hydro potential in the State it is neces-
accelerate hydro power development by
ing an organization entirely devoted to
power and multipurpose projects and
eparate allocations for hydro power. It is
y to employ cheaper and expeditious
of construction for dams and tunnels even
y involve importing technology. Large
pose and hydroelectric projects should be
ed that interim partial benefits are derived
nomical manner. Mini hydro schemes on
irrigation canals can fill up the gaps in
elopment period projects. Research and
ent programs for unconventional renew-
ces of electricity should be accelerated.

IZATION: A DECADE POINTS TO NGE,

rities Association, London (England).

eering and Management, Vol. 132,
, June, 1985.

*Water management, *England,
tewater treatment, *Water treatment,
ion, Water conveyance, Manage-
ng, Organizations, Sludge disposal,

In 1974 the responsibilities of over 1500 organizations for water supply, wastewater collection and treatment, and rivers were assumed by just ten autonomous water authorities in England and Wales. Additional changes are now being made, aimed at streamlining the water industry through changes made in the structure of the water authorities themselves. Training within the industry is now the job of the Water Industry Training Association, a company operating on commercial lines. A new central body was also established. Recent reductions in capital expenditures in real terms has brought about a greater emphasis on project appraisal. The water industry's first priority is to ensure that supplies are not a source of infection from harmful organisms. This involves the protection of sources, the disinfection of water supplies, and the monitoring of water in distribution systems. Britain's Water Research Center is now paying more attention to sludge disposal as well as sludge treatment in response to advice from water authorities. In considering future policy for sludge dumping in the seas around England and Wales, the water industry is most concerned in understanding the contribution made by sewage sludge to total polluting loads. The choice of sludge disposal routes is essentially a question of balancing risk avoidance against cost reduction. (Baker-IVI)

DETERMINATION OF URBAN FLOOD DAMAGES,

Corps of Engineers, Baltimore, MD. Baltimore District.
S. J. Appelbaum.
Journal of Water Resources Planning and Management, Vol. 111, No. 3, p 269-283, July, 1985. 8 Tab, 13 Ref.

Descriptors: *Flood damage, *Urban areas, *Computers, Utilities, Transportation, Emergency services, Housing, Commercial establishments, Costs.

A new methodology and computer program, DAPROG 2, have been developed by the Baltimore District, Corps of Engineers to estimate urban flood damages. Stage-damage relationships are computered for individual residential and commercial properties. These individual relationships are the aggregated into composite stage-damage relationships for an entire reach. For residential properties, replacement values for the structure and contents are estimated and applied to depth-percent damage relationships in order to develop stage-damage relationships. Regression equations have been developed to estimate structure replacement cost from physical attributes which are easily obtained in the field. Contents values are also estimated from the data obtained in the field. For commercial properties, standard stage-damage relationships for 67 types of businesses are used. Utility and transportation damages and emergency care costs are also computed. The computer program is interactive and allows the user to correct data errors online. The program has several optional features and reports which are selected by the user. DAPROG 2 has been successfully used by the Baltimore District in several flood control studies. DAPROG 2 has also been used by other Corps Districts and state agencies. (Author's abstract)

6G. Ecologic Impact Of Water Development

ABOUT A SOURCE OF NUTRIENTS IN THE TROPICAL RIVER RAJANG (N BORNEO) IN RELATION TO FUTURE IMPOUNDMENT,

Forschungsinstitut und Natur-Museum Senckenberg, Frankfurt am Main (Germany, F.R.).
A. Lelek.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2115-2118, 1985. 1 Fig, 9 Ref.

Descriptors: *Nutrients, *River Rajang, *Borneo, *Environmental effects, *Reservoirs, Water level, Water resources development, Resources development, Tropical regions.

Nutrients and organic matter in the large load of drifting vegetative debris in the Rajang River (North Borneo) could have serious negative consequences for the water quality within an impoundment if one were constructed in the upper reaches of this river. A distinctive characteristic of the Rajang River is its large, rapid changes in water level; daily changes of 3-5 m are the rule. This feature, combined with pulses of debris washed into streams by tropical storm runoff, creates a shifting load of vegetative debris, some of which contributes to the nutrition of fish and invertebrates in the river. The debris tends to be removed from the upper reaches of the river and moved downstream, where it accumulates particularly at the confluences with tributary streams. If an impoundment were constructed, this debris would wash into the impoundment, with potentially disastrous consequences for water quality (anaerobiosis, hydrogen sulfide release), particularly if existing vegetation is not removed from the affected area prior to flooding. It is recommended that vegetation be cleared from the zone to be flooded and that leaf traps be set up on tributary streams to trap forest litter so that it can become partly mineralized before carried into the man-made lake. ENERGY EXTRACTION FROM LAKE SEDIMENTS WITH HEAT EXCHANGERS. EFFECTS ON WATER QUALITY, SEDIMENT, BOTTOM FAUNA, AND FISH,

Lund Univ. (Sweden). Limnological Inst.
L. Leonardson.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2249-2253, 1985. 4 Fig, 13 Ref.

Descriptors: *Energy sources, *Resource development, *Environmental effects, *Water quality, *Lake sediments, *Benthos, *Fish, Heat transfer, Water temperature, Sediments, Midges.

Studies conducted over the winter-spring 1982/83 period showed that a closed pipe heat exchanger system caused no negative or positive changes in water quality, sediment-water interactions, or bottom fauna in a Swedish lake. It is possible that the lack of observed environmental effects resulted from the relative mildness of the winter of 1982/83 (only 1 mo of ice cover). Water temperature near the pipe was as low as 2 C, but sediment oxygen levels, sediment chironomid levels, and rates of chironomid emergence did not differ between the sediments containing the pipe field and the undisturbed area. In this study, 3,300 m of pipe of 40 mm outside diameter was laid out on the sediments of an experimental lake of 18,000 sq m surface area in southern Sweden. Two closed pipe systems were used, one sunk down in the lake sediments and one dug down in an adjacent field. Brine temperature during winter within the sediments was expected to be less than -5 C. This heat exchange system resembles the more than 600 closed-system heat exchangers for energy extraction from lake water or sediment that have been installed in Sweden from 1978-82. (Rochester-IVI)

EFFECTS OF IMPOUNDMENT AND DRAWDOWN ON THE FISH COMMUNITY OF A SOUTH AMERICAN RIVER,

British Columbia Univ., Vancouver. Inst. of

Animal Resource Ecology.
T. G. Northcote, M. S. Arcifa, and O. Froehlich.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2704-2711, March, 1985. 2 Fig, 3 Tab, 16 Ref.

Descriptors: *Americana Reservoir, *Atibaia River, *Brazil, *Fish populations, *Eutrophication, *Dam effects, Reservoir operation, Water resources development, Environmental effects, Population dynamics, Food chains.

The Americana Reservoir (Brazil) was formed by a 25 m high dam constructed on the Atibaia River, some 500 km above its confluence with the middle Parana. Limnological characteristics of the eutrophic and polymictic reservoir are well documented as are general effects of pollution from sewage and industrial outfalls. The Atibaia River prior to impoundment had a moderately rich fish community probably composed of some 90 species, mostly characoids and siluroids. Of the 65 species apparently no longer present 30 years after impoundment, over two-thirds were siluroids whereas a lower reduction occurred in the characoids, leaving a post-impoundment fish community dominated by this latter group. Not all the changes in the fish community following impoundment of the Atibaia River can be related to changes associated with the shift from lotic to lentic conditions. During this same period there also has been marked eutrophication of the system as well as severe pollution by heavy metals, phenols, herbicides and other materials. The recent and sudden drawdown of Americana Reservoir apparently did not produce major changes in relative abundance of many fish species. The reduction in conditions for the planktivorous Astyanax following drawdown may be a food chain effect related to the concomitant decline in phytoplankton and zooplankton abundance. (Baker-IVI)

HUMIC ACIDS IN THE INFLOWS TO THE FLAJE RESERVOIR AFTER DEFORESTATION OF ITS WATERSHED,
Vyzkumny Ustav Vodohspodarsky, Prague (Czechoslovakia).
J. Micka, L. Fiala, and J. Chalupa.
Acta Hydrochimica et Hydrobiologica, Vol. 13, No. 1, p 47-52, 1985. 3 Fig, 2 Tab, 3 Ref.

Descriptors: *Humic acids, *Deforestation, *Watersheds, *Flaje Reservoir, *Czechoslovakia, Air pollution, Peat bogs, Forest watersheds, Chemical oxygen demand, Color, Nitrates, Vegetation.

Flaje Reservoir (Czechoslovakia) was first filled in 1960. Water quality in the reservoir after filling was compared with that for the period 1976-1982. When the reservoir was first filled, 70% of the watershed was still covered by forests; at present only about 35% of the area is covered by forests and the large peat bogs are practically bare of trees. This deforestation was caused by air pollution from a nearby industrial region. The concentration of humic matter decreased from the original 8 mg/l to 4 mg/l. The relationships between the COD-Mn and humic acid concentration, and color can be described by a linear function. Parallel to deforestation, the nitrate concentration increased; this can be explained by the higher nitrogen concentration in precipitation. The improvement in color, COD, and humic acid concentrations after deforestation may be due to coherent plant growth that developed on the deforested surface of peat bogs and prevented the original erosion and eluation of the forest soil. RESERVOIR IMPACTS: A SYNTHESIS OF A 10-YEAR RESEARCH PROJECT,
Ohio Agricultural Research and Development Center, Wooster. Dept. of Agricultural Economics.
T. L. Napier, W. R. Goe, and M. V. Carter.
Water Resources Research, Vol. 21, No. 6, p 801-807, June, 1985. 34 Ref.

Descriptors: *Reservoirs, *Social aspects, Environmental effects, Water resources development, Ohio.

The purpose of this paper is to present a synthesis of research findings derived from longitudinal monitoring of a reservoir affected community group located in the urban fringe of a major metropolitan community in central Ohio. Data were collected at three time periods to assess the social impacts of rapid change on local people. Data were collected over a 10-year period using standardized measurement devices to ensure comparability of the information collected. The research findings demonstrate that extensive modification of social and physical environments did not result in the destruction of the social fabric of the affected group. Observations over time suggest that the affected group has accommodated many of the changes introduced in the community and has accepted the lake project. (Author's abstract)

GROWTH RATE OF YEARLING COLORADO SQUAWFISH AT DIFFERENT WATER TEMPERATURES,
National Fisheries Center-Leetown, Kearneysville, WV.
T. Black, and R. V. Bulkey.
Southwestern Naturalist, Vol. 30, No. 2, p 253-257, May, 1985. 2 Tab, 15 Ref.

Descriptors: *Water temperature, *Ecological effects, *Water resources development, *Squawfish, *Growth, Fish physiology, River basin development, Resources development, Animal physiology, Fish populations.

One of the major habitat changes imposed on the upper Colorado River drainage by dam construction was an altered annual water temperature pattern which results in much lower summer water temperatures in significant portions of the drainage. Specimens of the endangered Colorado squawfish, Ptychocheilus lucius, which have been caught in recent years have been half as long as specimens caught in the past; the change in annual river temperature has been cited as the possible cause of an apparent reduction in growth rate of the species. Research was conducted to determine the optimum growth temperature for Colorado squawfish and the relation between optimum growth temperature and final thermal preferendum for this species. Growth rate of yearling Colorado squawfish over a 12-week period was determined for fish held at 15, 20, 25, and 30 C with excess food. The effect of temperature on growth rate was highly significant; fastest growth occurred at 25 C. Fish gained about 0.3 gram at 15 C, 0.9 gram at 20 and 30 C. and 1.7 grams at 25 C during the 12-week period. Results suggest that 25 C, the final thermal preferendum, is the temperature at which Colorado squawfish grow fastest with abundant feed. Reduced water temperature below dams in the Colorado River drainage could well have lowered growth rate of Colorado squawfish from historic levels. Future water shortage and development projects should be designed to provide summer water temperatures as near the optimum growth level as feasible. (Collier-IVI)

mmunity of bacteria epiphytic on
ula erecta and Ranunculus tricho-
iphytic on exposed glass slides was
oligotrophic and a eutrophic site on
s (West Germany), a chalk stream.

Light microscopy and scanning electron microscopy were employed. Periphyton of the differently polluted zones showed characteristic 'Aufwuchs', depending on the time of exposure. Slides from the oligotrophic site revealed mainly cocci within 3 days, whereas those exposed in the eutrophic zone showed densely scattered rods and sheathed forms directly after exposure. The longer the exposure period, the more similar were the periphytic microfloras of the two sites, both in terms of size and forms. The bacteria on B. erecta and R. trichophyllus appeared to be concentrated in the grooves of the leaves. This epiphyton at the unpolluted site consisted mainly of rod-shaped cells and threads that showed remarkable similarity to the periphytic 'Aufwuchs' observed at the eutrophic site. Bacteria from the oligotrophic site may be considered as 'Kuemmerformen' (starved forms); they appear to develop into rods if exposed to higher nutrient supplies for a longer period. Nutrients derived from plants (or leaf exudates) may account for the smaller differences observed between epiphytic floras from polluted and unpolluted sites than between the glass slide microfloras from these sites. USE OF AQUATIC BRYOPHYTES TO MONITOR HEAVY METALS POLLUTION OF FRESHWATERS AS ILLUSTRATED BY CASE STUDIES,
Metz Univ. (France). Lab. d'Ecologie.
C. Mouvet.
Verhandlung Internationale Vereinigung Limnologie, Vol. 22, No. 4, p 2420-2425, 1985. 3 Fig, 3 Tab, 8 Ref.

Descriptors: *Bioindicators, *Bryophytes, *Heavy metals, *France, *Cance River, *Fensch River, *Bienne River, Metals, Water pollution effects, Bioaccumulation, Indicators, Arsenic, Cadmium, Copper, Iron, Lead, Zinc.

Applications of aquatic bryophytes as monitors of heavy metal contamination are illustrated by three case studies; a tannery, iron and steel plants, and metal coating factories. Along the Cance River (a tributary of the Rhone River, France), where tannery effluents were present, Platyhypnidium exhibited slightly higher contents of metals (As, Cd, Cu, Fe, Pb, Zn) than Fontinalis at most stations, but the downstream profiles were similar. Along the Fensch River (a tributary of the Moselle River, France), where steel rolling mills and blast furnaces are responsible for heavy metal inputs, new records were set for concentrations of metals in aquatic bryophytes (P. riparioides): 277 g Zn/Kg, 98 g Fe/kg, 15 g Cr/kg, 3.7 g Cu/kg, 2.9 g Pb/kg, and 187 mg As/kg. The record values of Fe, Cr, and As were obtained on bryophytes transplanted for just three days in the most polluted site. At the third site, the Bienne River (a tributary of the Ain River, France), where many small metal coating factories contribute pollution, it was possible to pinpoint individual sources of Cu among 13 metal coating factories located as little as 300 m apart. Aquatic bryophytes offer numerous advantages in pollution monitoring compared to other organisms such as phytoplankton, periphyton, macrophytes, and macroscopic algae. Bryophytes (Cinclidotus, Fontinalis, Platyhypnidium, Scapania, and others) are easily sampled and identified, have high concentration factors, are attached and perennial, tolerate high levels of toxicants, and show a highly significant correlation between their contents of heavy metals and concentrations in the water. Descriptors: *Measuring instruments, *Tritium, *Liquid scintillators, Water analysis, Calibrations, Sensitivity, Radioisotopes.

Twentyone glass and plastic counting vials and 15 liquid scintillators commercially offered for determining tritium in water have been examined with regard to their suitability. For this purpose a comparison of their characteristics has been made, including counting efficiency, quality quotient, figure of merit, calibration factor and sensibility of measurement arrangement and also the mean background for samples in several 20 ml counting vials at optimum mixing ratio of scintillator cocktail to water. From this comparison a qualitative assessment has been derived and on this basis suitable counting vials and liquid scintillator cocktails for determining high and low tritium contents (low level range) have been recommended. Descriptors: *Complexation, *Metals, *Chemical analysis, *Sediments, *Sludge, *Extraction, Lead, Copper, Zinc, Organic solvents, Sequential extraction, Sodium acetate, Ammonium acetate, Fate of pollutants.

The extractability from a purification sludge of organically bound Pb, Cu and Zn with various organic solvents is studied systematically. A significant part in the range of 10% of the whole content was found for Cu only. Liquid-liquid distribution of the ammonium and sodium acetate extracts from the standard sequential extraction procedure by organic solvents in combination with photometric direct determinations of the labile contents show that the metals Fe, Cu and Zn are complexed to different extents. The results of this differentiating analysis for some sludges and sediments are demonstrated. (Author's abstract)

RECONSTRUCTION OF A DAM WATER INTAKE UNDER CONDITIONS OF CONTINUOUS OPERATION OF THE RESERVOIR,
S. S. Golik.
Hydrotechnical Construction, Vol. 18, No. 10, p 484-489, October, 1984. 5 Fig, 1 Tab. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 10, p 20-23, October, 1984.

Descriptors: *Intakes, *Dam construction, *Reconstruction, Earth dams, Tunnels, Embankments.

In 1983, construction was completed on building up the barrier of a reservoir in the Crimea, consisting of a class II earth dam, retaining embankment, and concrete overflow dam. Simultaneously, the dam water intake was reconstructed. The reservoir was operated continuously as a water supply during the reconstruction period. The dam intake consists of a tunnel located under the dam, head and tail walls. Considerable deformation occurred in the intake tunnel after the first phase of filling the reservoir. The intake reconstruction involved reinforcement of the tunnel and dry chamber of the head wall, and the provision of intake at the increased useful storage level after the reconstruction of the reservoir. A continuous operation regime of the intake and deliver of water to consumers during repair of the structures was maintained. (Keenan-IVI)

MODEL FOR BEAM-MODE BUCKLING OF BURIED PIPELINES,
Texas Univ. at Austin. Dept. of Aerospace Engineering and Engineering Mechanics.
H. Yun, and S. Kyriakides.
Journal of Engineering Mechanics, Vol. 111, No. 2, p 235-253, February, 1985. 17 Fig, 1 Tab, 16 Ref. NSF grant CEE-8140043.

Descriptors: *Pipelines, *Beam mode buckling, *Compression, Seismic properties, Pipes, Mathematical models, Deformation, Buckling, Mechanical failure, Design criteria.

Large ground movements (such as fault movements, landslides, and sediment subsidence) can cause a line to develop compressive loads which can lead to buckling. Lines on the ground surface or buried in relatively shallow trenches tend to behave essentially as beams. Under compression, a section of the line lifts through the ground. An attempt is made to modeling the so-called 'beam mode buckling' exhibited under compression in pipelines. The line is modeled as a long heavy beam on a contacting surface. The reacting surface is modeled first as an elastic and subsequently as a rigid foundation, with the additional constraint that it only reacts to compressive loads. The problem is assumed to possess a localized imperfection. Under compressive axial load, a section of the beam lifts off the foundation. The problem is studied through a large deflection extensional beam nonlinear formulation. The large deflection response of the beam is found to exhibit a limit load which is shown to be imperfection sensitive. Numerical examples using actual pipe parameters clearly indicated that the limit load is reached with relatively small vertical and axial displacements of the beam. Provided the pipe continues to behave as a beam (i.e., the limit load is less than the shell-buckling load of the pipe), the pipe can sustain deformations well beyond the limit load without failure. Pipelines can be designed to ensure that in the event of excessive compression, they buckle out of the ground but remain operational and structurally sound. This can be achieved by designing periodically placed imperfections in the pipeline. (Moore-IVI)

SIMPLIFIED EARTHQUAKE ANALYSIS OF CONCRETE GRAVITY DAMS: SEPARATE HYDRODYNAMIC AND FOUNDATION INTERACTION EFFECTS,
Texas Univ. at Austin. Dept. of Civil Engineering.
G. Fenves, and A. K. Chopra.
Journal of Engineering Mechanics, Vol. 111, No. 6, p 715-735, June, 1985. 12 Fig, 20 Ref, 1 Append. NSF grants CEE-8120308 and CEE-84011439.

Descriptors: *Earthquakes, *Gravity dams, *Hydrodynamics, *Dam foundation, Concrete dams, Vibration, Reservoirs, Mathematical equations.

Simplified procedures are presented for the analysis of the fundamental vibration mode response of concrete gravity dam systems for two special cases: (a) Dams with reservoirs of impounded water supported on rigid foundation rock; and (b) dams with empty reservoirs supported on flexible foundation rock. In the first case, the effects of dam-water interaction and reservoir bottom absorption on dam response are included, whereas the effects of dam-foundation rock interaction are included in the second case. In each case, the response of the fundamental vibration mode of a dam monolith is modeled by an equivalent single degree-of-freedom system with frequency-independent properties chosen to represent the effects of complicated, frequency-dependent hydrodynamic terms or foundation-rock flexibility terms, as appropriate. The maximum earthquake-induced deformations and equivalent lateral forces can be computed using the response spectrum for a special ground motion. The procedures and results presented in this paper are extended in a companion paper to develop a simplified analytical procedure for concrete gravity dams that includes the simultaneous effects of dam-water interaction, reservoir bottom absorption, and dam-foundation rock interaction. (Author's abstract)

SIMPLIFIED EARTHQUAKE ANALYSIS OF CONCRETE GRAVITY DAMS: COMBINED HYDRODYNAMIC AND FOUNDATION INTERACTION EFFECTS,
Texas Univ. at Austin. Dept. of Civil Engineering.
G. Fenves, and A. K. Chopra.
Journal of Engineering Mechanics, Vol. 111, No. 6, p 736-756, June, 1985. 8 Fig, 10 Ref, 2 Append. NSF grants CEE-8120308 and CEE-8401439.

Descriptors: *Earthquakes, *Gravity dams, *Hydrodynamics, *Dam foundations, Concrete dams, Rock mechanics, Dam-water interactions, Reservoirs, Mathematical equations.

A companion paper presented simplified procedures for earthquake analysis of the fundamental mode response of concrete gravity dams including the separate effects of dam-foundation rock interaction and dam-water interaction with reservoir bottom absorption. These procedures are extended to develop a simplified analytical procedure for evaluation of the response of concrete gravity dams to earthquake ground motion including the simultaneous effects of dam-water interaction, reservoir bottom absorption, and dam-foundation rock interaction. Expressions for the parameters of an equivalent SDF (single degree-of-freedom) system that models the fundamental mode response of dams are derived, a procedure to implement the analytical procedure is outlined, and an extension to consider the response contributions of the higher vibration modes of the dam is briefly mentioned. The role of mechanized tunnelling in India is considered along with conditions under which it may be deployed and the experienced gained during the process in the maiden Indian hydroelectric project. India saw its first mechanized tunnelling operation in Loktak Hydroelectric Project in the State of Manipur. The 100 million dollar Loktak Hydroelectric Project situated in the Manipur State anticipates diversion of 58.8 cumecs of water from the Loktak Lake with a view to utilize 42 cumecs for generation of power with a gross head of 312 meters and supply of 16.8 cumecs for lift irrigation. The water will be diverted from the lake through a water conductor system comprising 2.27 km of open channel, 1.073 km of cut and cover section and 6.65 km long, 3.81 m finished diameter of horsehoe shaped head race tunnel terminating in the penstock manifold at the surge tank end. The three penstocks laid on the surface slope of the hill have an average length of 1346 meters each. The power plant situated at the bank of Leimatak river houses 3 units of 35 MW each. The tunnel traverses through lake sediments in the initial reaches followed by terrace deposits in about 1250 km length and splintery shales with subordinate sandstone and silt stone bands of Disangs and Barail Series in the remaining reach. A number of predominant faults have affected these rock formations with steep dip either towards east or west. The use of the Alpine Miner AM-50 is described, which is a selective cutting machine designed for operation in medium hard rock up to an unconfined compressive strength of about 1000 kg/sq cm. The machine can economically excavate a wide range of rocks encountered in underground mining and tunnelling. (Baker-IVI)

Descriptors: *Tunneling, *Construction equipment, *Excavation, Loktak Hydroelectric Project, Manipur, India, Hazardous conditions, Methane, Hydroelectric plants.

The work of tunnelling at the Loktak Hydroelectric Project, Manipur, India was suspended due to a methane gas explosion during excavation in 1975. In 1977, construction on two faces was resumed using two roadheader Alpine miners AM-50 (imported from Austria) A detailed study was made on the working of the machine, consumption of spare parts under different geological conditions, and the various practical problems. If the machine breaks down, it may not be possible to move it out until it is repaired. No arc welding or gas cutting is allowed inside the tunnel because it contains highly inflammable methane gas, which resulted in unanticipated delays. The machine is most suitable only where supporting system is of secondary importance and continuous excavation is possible so as to get maximum utilization of the machine. In tunnels where rock strength ranges from 150 to 400 kg/sq cm, after excavation the rock has to be supported immediately and the maximum time is taken for providing permanent supports. In soft ground conditions where seepage water is present, bogging down of the miner consumes most of the time and the operation must be carried out very carefully. (Moore-IVI)

THREE DIMENSIONAL FINITE ELEMENT STRESS ANALYSIS OF GRAVITY DAMS,
Indian Inst. of Tech., New Delhi.
D. K. Sehgal, R. Natarajan, and S. M. A. Kazimi.
Indian Journal of Power and River Valley Development, Vol. 33, No. 11, p 394-396, November, 1983. 4 Fig, 7 Ref.

Descriptors: *Gravity dams, *Finite element method, *Stress analysis, Computers, Model studies, Dams, Stress, Strain, Concrete dams.

Three dimensional finite element analysis of a concrete gravity dam block is done and results are compared with those obtained by a two dimensional finite element analysis. The geometry of a 100 m high concrete gravity dam was chosen for this study. The dam is divided into 49 elements with 246 nodes. Twenty noded, isoparametric, rectangular prism elements are used and displacements are allowed to vary in parabolic fashion. There are differences between the stresses predicted by 2D and 3D analysis. The major point of difference is the area of the tension zone. A 2D analysis shows a smaller tension zone surrounding the heel of the dam and upstream face of the foundation, whereas 3D analysis gives a much bigger tension zone. For the preliminary design of a dam, to save computer time and man time, one can go ahead with 2D analysis. However, for the exact analysis for final design, 3D analysis is recommended. This becomes almost essential for the cases where either the foundation is nonhomogeneous or the geometry of the dam changes along the longitudinal axis. This type of study keeps a stress analyst aware of the magnitude of inaccuracies involved in simple plane strain analysis for such problems. (Baker-IVI)

TOMORROW'S TECHNOLOGY FOR TODAY'S PROBLEMS,
Wessex Water Authority, Bristol (England).
K. F. Roberts.
Journal of the American Water Works Association, Vol. 77, No. 6, p 59-65, June, 1985. 5 Fig, 8 Ref.

Descriptors: *Water supply systems, *England, *Wales, *Wessex, *Management planning, *Administrative agencies, Water distribution, Water districts, Water mains, Maintenance costs, Sewer systems.

Since standards in Britain vary so greatly, even within a single network, and programs of asset replacement have only in more recent years been tackled in a planned and systematic way, the traditional problems of water distribution (peak demand, pressure variations, burst mains, unaccounted-for water) have increased in seriousness rather than having been overcome. The problems associated with aging underground distribution networks in the United Kingdom are being addressed at the national and regional levels. Some 80,000 burst pipes, excluding mains, are repaired each year, and the cost of these repairs is at least $75 million annually; most of the bursts occur in lines of 6 in. diameter or less, which represents 80% of the nation's distribution system. The 1974 reorganization of management of the entire water cycle in England and Wales created 10 regional water authorities whose boundaries were decided on the basis of natural water basin catchments rather than on artificial political or commercial criteria. The Wessex Water Authority's use of telemetry to reduce stresses on distribution networks and extend the life of underground assets is described. The potential effectiveness of renovation as an alternative to replacement was demonstrated by calculations that show that if renovation could be applied to two thirds of the system at, say, a third of the cost of replacement, then the total cost of overall replacement would be cut by nearly half. A major change in the financial regulations under which water authorities operate was introduced in Great Britain in 1982 with a move from historical- to current-cost accounting. (Collier-IVI)

DESIGN AND OPERATION OF A FUSE-PLUG SPILLWAY IN SWAZILAND,
Watermeyer, Legge, Piesold and Uhlmann, London (England).
E. T. Engels, and A. Sheerman-Chase.
International Water Power and Dam Construction, Vol. 37, No. 6, p 26-28, June, 1985. 4 Fig, 1 Tab, 4 Ref.

Descriptors: *Design criteria, *Spillways, *Fuse-plug spillways, *Swaziland, *Umbuluzi River, Water resources development, Dam construction, Costs, Floods.

The combination of a concrete-lined spillway and an emergency spillway with a two-level erodible bund control provided an economical accomodation of flood discharges resulting from Cyclone Domoina, which deposited more than 400 mm of rain on the catchment above the Umbuluzi River dam at Mnjoli, Swaziland. Within less than half an hour, the double-bund fuse plug washed out, and the spillway opened. Topsoil and vegetation in the valley below the spillway were washed away in a strip about 120 m wide, and the flood eroded a channel some 40-60 m side and up to 10 m deep. The dam was not damaged, nor was their unacceptable loss of freeboard as a result of this flood event. The emergency spillway operation was entirely controlled by the water level, with no human intervention. The spillways at Mnjoli cost $1,118,800 (1977 prices), of which 63% was for the concrete spillway and 37% for the emergency spillway with the erodible fuse-plug bunds. The cost of reinstatement of the erodible bunds in the emergency spillway is estimated to be $40,800 (1984 rates), and to replace a waterline and gravel road below the spillway that were washed away will require an additional $9,100. POWER CONDUITS FOR HIGH-HEAD PLANTS,
Innsbruck Univ. (Austria). Inst. fuer Konstruktiven Wasserbau und Tunnelbau.
G. Seeber.
International Water Power and Dam Construction, Vol. 37, No. 6, p 50-54, June, 1985. 10 Fig, 12 Ref.

Descriptors: *High-head storage plants, *Pumped storage, *Pressure tunnels, *Tunnels, Tunnel lining, Stress, Design criteria, Pipelines, Concrete, Unlined tunnels, Construction joints, Construction materials.

Loading of pressure tunnels and shafts, and lining techniques are reviewed, with particular reference to the problems existing in plants of large size (600-700 MW), heads of up to 1,000-1,500 m, and dam heights up to 300 m. Increases in hydrostatic load have not been the main source of problems in these new plants, rather, it has been the increase the dynamic, or pulsating load, that has caused problems in conduits. Introduction of automatic control equipment has meant more abrupt changes in operating conditions. Incorporation of a reverse-flow control throttle (Thoma throttle) in the surge chamber has helped reduce large oscillation in this area. Operation in the pumping mode involves higher frequency, but smaller amplitude pressure waves which quickly lead to alternating stress numbers greater than 10 to the 10th power. Imposing operating restrictions or incorporating damping elements are ways to reduce dynamic load in peak-load stations. Rock pressure cannot be counted on as a counteracting external force to equalize pressure on the inner lining of conduits. Only groundwater pressure can be incorporated into lining calculations as a pressure relief, particularly where it is higher than the turbine water pressure. Lining techniques suitable for high-pressure power conduits include no lining in suitable rock and concrete linings, of which the latter are particularly common in the Alps. In unlined tunnels there is no groundwater support pressure, requiring that more emphasis be placed on adequate primary pressure, that is, overburden thickness. Cooling and shrinkage deformations of concrete tunnel linings can lead to contractions approximately double the proof strength of the concrete, leading to cracks or gaps. Grouting can be employed to add the mechanical strength of the rock mass to that of the concrete, thus enabling much higher pressures to be absorbed. Almost double the internal pressure can absorbed with such a design under average site conditions, but such concrete linings have the disadvantage that they are subjected to high levels of continuous tensile stress during operation. DAMMING THE VOLGA CHANNEL AT THE CHEBOKSARY HYDROELECTRIC STATION,
B. M. Erakhtin.
Hydrotechnical Construction, Vol. 18, No. 10, p 465-472, October, 1984. 4 Fig, 7 Tab. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 10, p 6-12, October, 1984.

Descriptors: *Dam construction, *Hydroelectric plants, *Volga Channel, *Cheboksary hydroelectric station, *USSR, Evaluation, Planning, Construction, Hydraulicking, Berms, Scour.

The Cheboksary hydroelectric station is the fifth and final step of the Volga transport-power cascade. The frontal, pioneer, and bermless methods were examined as possible damming methods. It proved to be technically possible to use the pioneer method for damming large rivers such as this, with erodible channels with depths of 18 m, discharges to 3000-3500 cu m/sec, and a drop of about 60 cm. The economic expediency of such damming should be determined in relation to the cost of stone at the construction site. Damming of large rivers with the use of hydraulicking is possible during intense ice formation. In the case of an erodible channel it is necessary to dump the berm from both banks simultaneously to prevent deep scouring of the bottom. To reduce consumption of stone materials, it is expedient to carry out hydraulic filling of the underwater part of the dam simultaneously with dumping the berm without lagging behind it. In the case of pioneer damming of rivers with an erodible channel, reliable protection of the bottom of the gap is necessary. Protection by a train of stone and rubble with a thickness of 1 m is no guarantee against scouring. The size of the stone of the train should correspond to the velocity in the gap. It should be dumped as an even layer without the formation of mounds. In the case of dumping a berm skeleton composed of large concrete blocks and elimination of the construction of a filter on its upstream slope, the formation of individual washouts at the site of closing the gap, threatening the integrity of the berm, is possible after completing the works. CHEREPNOV WATER LIFTER: THEORY AND EXPERIMENT,
Missouri Univ.-Columbia. Dept. of Civil Engineering.
H. Liu, M. Fessehaye, and R. F. Geekie.
Journal of Hydraulic Engineering, Vol. 111, No. 6, p 951-969, June, 1985. 7 Fig, 1 Tab, 10 Ref.

Descriptors: *Cherepnov water lifter, *Hydraulics, Hydraulic machinery, Mathematical equations, Computers, Water lifter, Potential energy, Head loss, Pumps.

The Cherepnov water lifter is a novel device to lift or pump water using the potential energy of water. A Cherepnov lifter is similar to a hydraulic ram in that the energy for pumping water comes from water, and that a portion of the inflow must be discharged to a lower place in order to lift the remaining portion of the inflow. The lifter is free of vibration and noise, and has little abrasion of parts. A theoretical and experimental investigation of the hydraulics of the little-known Cherepnov water lifter was conducted. As many as 36 algebraic and differential equations are required to predict the cyclic motion of the flow going through the lifter. With these equations, the behavior of the lifter can be conveniently analyzed on any computer having the Continuous System Modeling Program capability. Accurate predictions can be made using this approach if the head-loss coefficient of each pipe of the lifer is determined accurately. For simplicity, the head-loss coefficients can be assumed without introducing significant errors. Although more research is needed to standardize the lifter design and to evaluate its performance under field conditions, it is felt that enough has been learned to warrant the use of the lifter, at least on a trial basis. It is recommended that a computer simulation of the lifter behavior for each particular design be conducted prior to constructing any lifter. (Moore-IVI)

PUMPS CRUCIAL TO SUCCESS OF LONG-DISTANCE AQUEDUCTS,
McGraw-Edison Co., Mountainside, NJ.
I. Karassik.
Water Engineering and Management, Vol. 132, No. 6, p 35-38, June, 1985. 2 Fig, 1 Tab.

Descriptors: *Water conveyance, *Aqueducts, *Pumps, Water supply, Water transport, Pipelines, Costs.

Pumping technology for long-distance transmission of water is receiving deserved attention as the need to transfer supplies of this essential resource increases throughout the world. In selecting pumps, first costs, construction costs, operating costs, and maintenance must be carefully considered. Some problems in pipeline design are reviewed, including pumping over long distances, and pumping through hilly or mountainous countryside. The number of pump stations that should be installed can be determined based on the pipeline capacity and the route which it is to follow. The possibility of providing multiple units for each station and whether they should be joined in parallel or series must be considered. This analysis must be made on the basis of the range of capacities over which the pipeline will operate throughout its projected lifetime, in conjunction with the total head requirements at these varying capacities. Single-stage or multi-stage pumps are available. (Baker-IVI)

ADVANTAGES OF TURGO-IMPULSE TURBINES IN MICRO-HYDEL UNITS,
Central Electricity Authority, New Delhi (India).
R. K. Grover.
Indian Journal of Power and River Valley Development, Vol. 33, No 1-2, p 7-8, January-February, 1983.

Descriptors: *Turbines, *Impulse turbines, *Francis turbines, *Micro-hydel units, Hydraulic equipment, Mechanical equipment, Design criteria, Planning, Suspended solids.

A point by point comparison is made between the turgo impulse turbine and the Francis turbine. The turgo-impulse turbine is a very simple prime mover. In Francis turbines, the water is admitted through ten to twenty or more openings and controlled by a number of carefully shaped adjustable guide vanes, which is a cumbersome arrangement. In impulse turbines, the runner is set about 1.5 m above the tailwater level, so it rotates in air at atmospheric pressure. In Francis turbines, a seal is a must as the runner rotates in a pressurized chamber. Generally the running water contains suspended matter and solid particles. At high velocity and pressure, this results in wear and tear. In impulse turbines, the parts that wear out are the tip of spear, the nozzle, and after a longer period, the runner. In high head Francis turbines, the suspended particles cause rapid wear and tear. In passing through fine clearances between guide vanes and end-cover facings, and worse still between runner and clearance rings, it can quicky reduce overall effficiency by several percent. One of the major advantages of the impulse turbine is the easy accessibility of various parts for inspection and maintenance. Governing of the unit is also relatively simpler in the case of impulse turbines. The impulse turbine loses to the Francis on three points: low specific speed, head loss due to suction head, and head variation permissible 20% as compared to 25 to 35% in the case of Francis turbines. (Baker-IVI)

PROBLEMS AND PROSPECTS OF POWER EVACUATION MANAGEMENT FROM HYDRO STATION IN HIMALAYAN RANGES,
Uttar Pradesh State Electricity Board, Dehra Dun (India).
T. C. Agarwal, V. N. Rikh, A. K. Gupta, and G. L. Tandon.
Indian Journal of Power and River Valley Development, Vol. 33, No. 3/4, p 87-92, March/April, 1983. 1 Fig.

Descriptors: *Hydroelectric plants, *Himalayas, *Mountainous regions, *Electrical transmission, Transmission lines, Transmission towers, Planning, Construction, Switchyards, Landslides.

The Himalayas have an immense reusable energy potential, which will be tapped by a number of hydroelectric projects, most of which are located deep in the hills. Most of the hydroelectric projects which are either under construction or investigation are located in difficult hilly terrain. Some of these schemes will have very high installed capacities. Location of hydroelectric power stations in such difficult terrain presents problems in the construction of transmission lines. Landslides frequently encountered in Himalayan ranges can result in tower failure. It appears preferable to have single circuit instead of double circuit lines, since in double circuit lines there can be complete outage of both the circuits in the event of tower failure. Proper planning for the routes of transmission lines is essential for ease of construction and maintenance in hill regions. Pooling stations are useful for groups of power stations to keep the step-up voltage at individual power houses low, in order to minimize the switchyard area. The use of bundle conductor lines with special large conductors is recommended for short distances between pooling stations and individual power houses. In cases of installations where flat land is not available for construction of a switchyard, the cost of installing underground gas insulated switchgear can be less than the conventional switchyard. This cost can further be reduced by keeping the SF6 switchyard in the construction adits of underground power houses which become redundant after construction. (Moore-IVI)

MODERN TRENDS IN MANUFACTURING LARGE FRANCIS TURBINE RUNNERS,
National Hydroelectric Power Corp. Ltd., New Delhi (India).
B. S. K. Naidu, and V. K. Gahlot.

Group 8C—Hydraulic Machinery

Indian Journal of Power and River Valley Development, Vol. 33, No. 11, p 386-393, November, 1983. 7 Fig, 3 Tab, 8 Ref.

Descriptors: *Turbines, *Turbine runners, Hydraulic turbines, Hydraulic machinery, India.

The world over, the unit capacities of hydraulic machines used for power generation and pumped storage are increasing day-by-day. The trend of constructing large units has particularly been persisting in the Francis range. With increased unit output, large runners are required to be manufactured and transported. The paper attempts to review the manufacturing involvements, materials, inspection methodology, transport limitations, site fabrication and other related aspects pertaining to the production of large runners (D > 3 m). Integrally cast, split construction, cast welded and stamp welded variants have been discussed with respect to the technology of manufacture, bringing to light the merits and demerits of each. The statistical data of large Francis runners produced by BHEL (Bharat Heavy Electrical Limited) and other leading world manufacturers have been given. Scope of application of such runners in Indian projects is discussed together with BHEL's strategy to meet the country's requirements. (Author's abstract)

ENERGY STORAGE: DEVELOPMENTS IN PUMPED-STORAGE,
Ecole Polytechnique Federale de Lausanne (Switzerland). Inst. de Machines Hydrauliques.
P. Henry, and J. E. Graeser.
International Water Power and Dam Construction, Vol. 37, No. 6, p 13-16, June, 1985. 5 Fig, 1 Tab.

Descriptors: *Energy storage, *Pumped storage, Energy conversion, Electric power production, Electrical equipment, Electric power demand, Engineering, Generators.

Of the methods available for energy storage, pumped storage has been widely preferred as it offers significant advantages. The complete transformation process gives an overall energy output generally higher than 70%; in spite of this the operation is profitable since the cost ratio of slack period and peak period power can be three or even four to one. The concept and history of pumped storage installations in Europe is reviewed. Technological developments are such that the construction of new facilities, particularly in Western Europe, is promising. The possibility of integrating new machines into existing pumped-storage systems makes this type of energy storage economical. Pumped storage will remain the most reliable and economical means of storing large quantities of energy for a relatively long time. (Keenan-IVI)

TESTS ON A FRENCH ADJUSTABLE TWO-STAGE PUMP-TURBINE,
Electricite de France, Chambery. Electrical and Mechanical Div.
N. Roche, D. Lefervre, P. Robert, P. Jarriand, and J. Rondon.
International Water Power and Dam Construction, Vol. 37, No. 6, p 21-25, June, 1985. 12 Fig, 1 Tab.

Descriptors: *Turbines, *Design criteria, *Pump-turbine, Testing, Pumped storage, Hydraulic machinery.

A test program conducted with a prototype pump-turbine with two adjustable stages has provided results that will permit development of high-output pump turbines with two adjustable stages to equip pumped-storage plants with operating heads of more than 1,000 nm. The average-output prototype unit was designed to operate at between 433 and 443 m gross head in both pumping and generating modes and to have an output when generating of 38 MW and when pumping of 33 MW; rotational speed in both modes is 750 revolutions per minute (rpm) and transient speed is 1,170 rpm (generating) or 1,120 rpm (pumping). The unit used two distributors and two 8-blade, stainless steel runners. Tests were made with the two distributors at different openings, and included some of the following conditions: (1) under normal conditions and load rejections in both generating and pumping modes, with distributors synchronized, (2) under normal operations and load rejections in both modes, but with different distributor openings, (3) load rejections with one distributor locked to various opening positions, (4) shutdown and load rejections with spherical valve closure distributors being locked in position (5) back-to-back startup of the machine by one of the Pouget units (35 MW Pelton, 250 MW Francis turbines) to investigate brake-pump and reversed pump rotation quadrants and (6) finalization of dewatering/rewatering sequences and operations as a synchronous condenser in both rotational directions. Testing at the relatively low head Truel (Tarn River, France) site was conducted for convenience, but this Neyrpic-Eketricite de France machine design is intended for employment under heads ranging from 800 to 1,500 m, with a maximal output of about 30 MW per unit. EARTHWORKS AT THE INGURI HYDRO-ELECTRIC STATION CONSTRUCTION SITE,
G. Y. Zarandiya, L. S. Babuniya, N. N. Shartava, N. Z. Kolbazov, and U. I. Godzhiashvili.
Hydrotechnical Construction, Vol. 18, No. 8, p 382-389, August, 1984. 3 Fig, 3 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 8, p 42-47, August, 1984.

Descriptors: *Earthworks, *Dam construction, *Excavation, Tunneling, Hydroelectric plants, Underground structures, Penstocks, Tailrace, Mountainous areas, Roads, Drilling.

At the Inguri hydrostation construction site, the bulk of the earthworks is accounted for by the foundation pit of the 271.5 m high arch dam and underground structures, consisting of the pressure diversion tunnel, five penstocks, two butterfly-valve chambers, the underground powerhouse and the tailrace tunnel. Details of the earthworks associated with the construction of the Inguri Hydroelectric Station are presented. It is recommended that for construction in mountainous areas, the roads leading to the foundation pit should have a minimum of cuts, be constructed on trestles, or pass through tunnels on the slopes. During excavation of the pit it is expedient to construct a concrete support for the finished sections of the pit as the earthmovers descend toward the river channel. During the excavation of the underground structures of the hydrostation, the use of highly productive drilling and mucking equipment and heavy-duty vehicles made it possible to accelerate the construction process. For the excavation of the powerhouse chamber, optimization of the plan for transporting the loosened rock to the surface with the maximum use of all vertical and horizontal accesses promote simplification and acceleration of the operations. **NONLINEAR DYNAMIC ANALYSES O[F]
EARTH DAM,**
Princeton Univ., NJ. Dept. of Civil Engine[ering]
J. H. Prevost, A. M. Abdel-Ghaffar, and S. J. Lacy.
Journal of Geotechnical Engineering, Vol[.]
No. 7, p 882-897, July, 1985. 12 Fig, 4 Tab, [refs.]
NSf grant CEE81-20757.

Descriptors: *Earth dams, *Earthquakes, *D[ynam]
ic analysis, Computer models, Stress, Strain celeration, Deformation, Vibration.

Earth dams are large three-dimensional nonl[inear] geneous structures constructed from zoned [earth] tic material; therefore, the computation or p[rediction] tion of their dynamic responses to earthquake ing is extremely difficult. The results of 2D n[onlinear] ear and 3D nonlinear dynamic finite element [analy]ses of an earth dam subject to two very dif[ferent] input ground motions are compared. A compa[rison] between measured and computed earthquak[e re]sponses of the dam is also presented. The stu[dy] based on rigorous nonlinear hysteretic an[alysis] utilizing a multi-surface plasticity theory. backbone shear stress-strain curve is assume[d hy]perbolic and symmetrical about the origin. tailed comparisons of induced stresses, strain celerations, and permanent deformations at va[rious] locations in the dam are presented. Only differences are found between the results o[f the] and 3D nonlinear analyses. The difference somewhat pronounced in the upstream-d[own]stream direction for the strong shaking case study demonstrates the importance of three-di[men]sionality on the dynamic earthquake respon[se of] earth dams, particularly in computing resu[lting] permanent deformations. For the moderate sh[aking] case, there is reasonable good correlation be[tween] the crest acceleration time histories computed the 2D and 3D nonlinear dam models. Some d[iffer]ences are observed for the strong shaking m[otion] in crest acceleration time histories, induced st[rong]

s in the dam material and resulting per-
eformations. The 3D nonlinear analyses
l orders of magnitude more expensive
2D counterparts. The 3D analyses are
ols to account for all possible vibration
the dam and all three components of
aking, to realistically predict the dam
nd to provide longitudinal response pa-

3, No. 5/6, p 181-187, May-June,
Ref.

Descriptors: *Hydraulic fracturing, *Soil physical properties, Confining stress, Saturated soils, Unsaturated soils.

An experimental investigation has been carried out to study the hydraulic fracturing phenomenon in soils. Cylindrical specimens have been tested under various cell pressures in a triaxial testing apparatus. Internal pressure is gradually applied through a needle inserted axially in the specimen until failure occurs while external pressure is kept constant. Tests are conducted for saturated as well as unsaturated soil specimens. In order to corroborate the experimental results, a theoretical analysis considering linear, elastic behavior of the soil is also carried out. It is considered that hydraulic fracturing will take place when the effective stress in the soil mass is tensile and equals the tensile strength of the soil. Linear relationship of hydraulic fracturing pressure and confining stress is obtained both theoretically and experimentally. The theoretical results show somewhat lower values compared with those obtained experimentally. It is observed that hydraulic fracturing pressure required to cause cracking is more than the confining stress. (Author's abstract)

MANAGEMENT OF MUD, PROBLEMATIC IN THE FOUNDATIONS OF CHANDAN AND GETALSUD EARTH DAMS IN BIHAR (INDIA),
Masan Dam Investigation Div., Bagaha (India).
C. Singh.
Indian Journal of Power and River Valley Development, Vol. 33, No. 9/10, p 309-311, 308, September/October, 1983.

Descriptors: *Earth dams, *Mud, *Chandan Dam, *Getalsud Dam, *India, Soil properties, Dam foundations, Dam construction.

Getalsud Earth Dam across the river Subernarekha in Ranchi District of Bihar was constructed during 1966-69 to intercept 725 sq km of unobstructed catchment of the Subernarekha below Matia Dam for hydel generation and additional water supply to Ranchi township. The mud, found or formed in the foundation of the earth-fill dam was troublesome. The mode of management depended upon the accessibility, the workability, the available time and the extent of security to be ensured. The natural drying, the impregnation of coarse grained heavier materials and squeezing out of excess water by porous material loading were among the main corrective measures practiced in Chandan and Getalsud Earth Dams, in which heavy duty towed scrapers and dozers were intelligently used for removal of mud. In most cases the management of the mud problem lay in heavy earthmoving machinery and not in manual labor. (Baker-IVI)

G. G. K. Moorthy.
Indian Journal of Power and River Valley Development, Vol. 33, No. 9/10, p 312-319, September-October, 1983. 10 Fig, 5 Tab, 8 Ref.

Descriptors: *Earth dams, *Earthworks, *Reinforced earth, Soil physical properties, Stress, Friction, Strength, Dam construction, Costs.

Reinforced earth is an economical means of improving the mechanical properties of the basic material, earth, by reinforcing it in the directions in which it is subject to the greatest stresses. The essential phenomenon in reinforced earth is the friction between the earth and the reinforcements. Through this friction, the earth transmits to the reinforcements the stresses which develop in the mass; the reinforcements are thereby placed in tension and the result is as though the earth possessed a cohesion in the directions in which the reinforcements are placed. This cohesion which is generated is directly proportional to the tensile strength of the reinforcements. The soil used in a reinforced earth structure should meet certain minimum criteria to ensure the development of sufficient friction between the earth and the reinforcements, and to ensure that no interstitial pore water pressures develop within the reinforced earth structure. The size, spacing and length of reinforcing strips are determined by calculation of internal stability of the reinforced earth structures. The flexibility of the reinforcing strips and their tensile strength are the essential elements in these calculations. The service life of a reinforced earth structure depends primarily on the resistance of the reinforcing strip to soil corrosion. Costs of reinforced earth construction are briefly considered along with advantages to using the reinforced earth technique for dam construction. (Baker-IVI)

8E. Rock Mechanics and Geology

WAYS OF USING THE BEARING PROPERTIES OF A ROCK MASS WHEN DESIGNING UNDERGROUND HYDRAULIC STRUCTURES,
V. F. Ilyushin.
Hydrotechnical Construction, Vol. 18, No. 8, p 357-364, August, 1985. 4 Fig, 7 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 8, p 21-25, August, 1984.

Descriptors: *Rock mechanics, *Design criteria, *Hydraulic structures, *Underground structures, Construction, Rock properties, Site selection, Geology, Linings, Coatings, Seismicity, Pressure, Groundwater.

One of the main principles of developing economic layouts and designs of underground hydraulic structures is the use of the bearing properties of the surrounding rock mass. With consideration of the available design, construction, and operating experience and tendencies toward an improvement of underground hydraulic structures, a number of general and particular directions can be followed. One of the first stages is the analysis of the engineering-geologic conditions of the construction territory and selection of the site of the underground hydraulic structure. Measures should be taken to make the best use of the rocks, including: artificial stabilization of rocks; efficient structure layout; use of shapes which are the most stable under the given conditions; and the use of linings and coatings. Seismic factors must also be taken into account. Laboratory investigations should be conducted on large-scale and two- as well as three-dimensional models permitting a reliable determination of the stress-strain state of the structure. Driving technology can be used to provide minimum disturbance of the rocks in the vicinity of the working. Inspection during and after construction is essential for underground structures. A number of underground hydraulic structures along with examples are given: structures experiencing rock pressure; pressure structures absorbing groundwater pressure; and outlet structures. GENERALIZED RELATIONS BETWEEN STATIC AND DYNAMIC INDICES OF ROCK DEFORMABILITY,
A. I. Savich.
Hydrotechnical Construction, Vol. 18, No. 8, p 394-400, August, 1984. 5 Fig, 2 Tab, 15 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 8, p 50-54, August, 1984.

Descriptors: *Deformation, *Rock properties, Seismic properties, Acoustic properties, Elasticity, Rock testing, Rock mechanics.

Seismic acoustic methods have been used to study the elastic and deformation properties of rock masses. The correlation between the characteristics of the medium determined in the seismic acoustic investigation and the indices of its deformation properties (the static modulus of elasticity and modulus of deformation) are the basis of a quantitative evaluation fo the indices of rock deformability. When solving many problems in practice, the deformation properties of rocks in their natural occurrence can be determined with sufficient accuracy from the data of seismic acoustic measurements

without conducting labor-intensive and costly static tests. (Keenan-IVI)

STRESS-STRAIN STATE OF EARTH DAMS ON UNDERMINED TERRITORIES,
V. F. Markevich, V. I. Teleschev, and A. K. Bugrov.
Hydrotechnical Construction, Vol. 18, No. 10, p 472-477, October, 1984. 3 Fig, 10 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 10, p 12-15, October, 1984.

Descriptors: *Mining, *Dam stability, *Earth dams, *Foundation failure, Dam failure, Construction, Dams, Embankments, Stress, Strain, Deformation, Tension cracks.

Underground mining causes deformations of the ground surface and affects engineering structures falling in the zone of influence of mining operations. Detection of the possibility of undermining of the foundations of earth dams is related to an investigation of their stress-strain state in the presence of deformations of the foundation being undermined, establishment of the limit values of these deformations, and development of special protective measures ensuring the normal operation of the dams in the presence of deformations exceeding the limit. A method is proposed for calculating the stress-strain state of earth dams and embankments located on foundations being undermined. As a result of the mathematical investigations the characteristics of the development of limit equilibrium zones and changes in all components of the stress-strain state were stablished. A substantial effect of the curvature of convexity of the foundation was found and the values of the limit strains of the foundation for homogeneous dams of cohesive soils with a dam height of 10-30 m were estabished. The occurrence of tension cracks in earth dams during undermining of the foundations represents an additional danger in connection with the fact that they are concentrators leading to the development of strains and eventually to growth of the crack. ELASTIC DEFORMATION OF THE FOUNDATION OF THE BRATSK CONCRETE DAM,
V. G. Ivanov.
Hydrotechnical Construction, Vol. 18, No. 10, p 492-495, October, 1984. 2 Fig, 1 Tab, 3 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 10, p 25-27, October, 1984.

Descriptors: *Deformation, *Dam foundations, *Settlement, Concrete dams, Reservoir operation, Bench marks, Rock mechanics, Elastic deformation.

Measurements of settlement of structures at the Bratsk hydroelectric station have been conducted since the start of filling the reservoir (September 1961). Analysis of the data yielded several results. Recommendations are made regarding the required degree of accuracy in measuring settlement. After filling the reservoir, more accurate methods become necessary. It is necessary to consider whether near-by bench marks are in the zone of deformation of the rock foundation. If so, this will distort the results. At this hydrostation with relatively small drawdowns of the reservoir it was possible to detect elastic behavior of the rock foundation of the dam. (Keenan-IVI)

Descriptors: *Dam foundations, *Site selection, *Reservoir siting, India, Planning, Evaluation, Dam construction, Decision making.

Methods currently in use in developed countries for reconnaissance and investigations of rock foundations for large dams are reviewed. The various in situ investigation methods in practice in European countries include: structural geology survey; graphical presentation of structural geology; geophysics; petite sismique; rock quality designation; Lungeon test; and Jacking test. Some of the methods are already in use in India, while some can be suitably modified according to Indian conditions. Stress should be laid on investigation methods which are expeditious and yield reliable results so that hydel projects which have a longer gestation period in India can be commissioned within 6-8 years instead of 10-15 years which is the case for many of the ongoing projects. Accuracy of the investigation is also desired so that the predictions made by geologists are not unreliable which sometimes leads to serious construction problems not anticipated originally and leads to adoption of a new method of construction, increasing the quantum of work, thus leading to an increase in estimated costs and extending the construction schedule. ON-SITE TESTS OF A NEW TYPE OF TUNNEL LINING AT THE NUREK HYDROSTATION CONSTRUCTION SITE,
V. V. Rukin, and V. L. Kuperman.
Hydrotechnical Construction, Vol. 18, No. 8, p 345-356, August, 1984. 13 Fig, 19 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 8, p 13-20, August, 1984.

Descriptors: *Tunnel linings, *Linings, *Latex concrete, Concrete technology, Elasticity, Deformation, Strength, Tunnels.

The maximum use of the bearing capacity of the rock mass is one of the principal ways to reduce the thickness of linings of hydraulic pressure tunnels. A new material, latex concrete, can be used to allow the rock to absorb the load from the internal pressure of the water because it can provide the necessary yielding and elasticity at a high tensile strength. The addition of synthetic styrene-butadiene latex SKS-65GP to the concrete mix in the amount of about 10% of the dry weight of the cement leads to a decrease of the modulus of deformation of concrete by more than two fold. The addition of latex to concrete makes it possible to reduce the water/cement ratio and to improve the technological properties of the concrete mix - fluidity, plasticity, and workability. Latex concrete can be prepared in ordinary concrete mixers and does not cause additional difficulties in concrete works. Large-scale investigations in an experimental gallery of tunnel 9-TTs at the Nurek hydrostation construction site were undertaken to obtain the data on the work of a tunnel with latex concrete in contact with massive rock and to perfect the technological parameters of concreting. The high elasticity of the latex concrete in comb
with its increased ultimate tensile strength
possible to reduce the thickness of latex c
linings compared with ordinary concrete
least half. For the permanent headrace tu
the Nurek hydrostation show that the use
latex concrete makes it possible to dispen
reinforcement of the lining and to use co
tion grouting of the rock with a total savin
million rubles. In the near future latex c
will be used in the linings of hydraulic str
(pressure tunnels) at a number of instal

concrete, *Concrete temporary support, *T
Construction, Linings, Hydroelectric plants.

The cast-in-place concrete temporary
(CTS) constructed by means of traveling
work can be used to solve problems of
acutely scarce metal (metal arches) and to p
safe underground working conditions in
stable rocks. Two types of CTS are currentl
a support capable of performing the func
permanent lining and a support contructed
period prior to the construction of per
lining. The CTS has been used in a num
hydrostation projects. The use of CTS is
mainly to determination of weak stability
tions of the rocks being tunneled. The possib
rockfalls depends not only on the strength
rock mass but also on the cross-sectional sha
span of the tunnel and length of its unsup
section. Therefore, the selection of the l
distance of the CTS from the face is imp
The reliability of the CTS is also determi
the forces of the bearing pressure of the ro
the arch on the rocks in the tunnel face and
constructed support behind the face. The CT
be used in rocks with a strength coefficie
than 2 and specially in zones of tectonic de
tions. The stability of the rocks should be e
ed and analog methods as well as laboratory
eling should be used. Moreover, additional
tory and on-site investigations are needed f
veloping calculations for CTS and the constr
technology. (Shieh-IVI)

of reduced discharge on emigration, growth, production, and distribution of ng rainbow trout, Salmo gairdneri, ed in small, seminatural experimental New Zealand. Three stream channels t discharges of 0.125 cu m/s from mid- spring in southern hemisphere) to mid- Discharge was then reduced in two ut remained unchanged in the third. f discharge by 32% (to 0.085 cu m/s) (to 0.050 cu m/s) caused no increase in emigration, the emigration rate imme- re reduction being 0.1-0.7 fish/d and nths after reduction being 0.0-0.3 fish/ , the results may have been influenced population sizes in the channels before es were altered. Presumably, these dif- re caused by unequal hatching success ted in the channel substrates. Popula- was greatest (41/100 sq m) in the cted for control discharge. Following discharge alteration, this pattern continued (lowest discharge: 21/100 sq m; control: 7/100 sq m). Fish size differences between channels at the end of the experiment (7 July) were in direct relation to channel discharges and in inverse relation to population density (largest fish in the control and smallest fish in the low discharge channel). Reductions in instantaneous growth rates were attributable to reduced discharge, but occurred about 2 months after discharge reduction. Reduced discharge depressed production after about 1.5 months and by the end of the experiment there had developed a direct relationship between discharge and production; production was 1.4 g/100 sq m at 0.125 cu m/s and -3.8 g/100 sq m at 0.050 cu m/s. There were no significant differences among the channels in the distribution of fish among riffle, pool, and run habitat types. Before discharge reduction, fish in all channels occurred mostly in the riffles and, after reduction, fish in control and treated channels became progressively more evident in the pools. Discharge reduction had no effect on this distribution. (Author's abstract)

SWIMMING PERFORMANCES OF THREE RARE COLORADO RIVER FISHES,
Utah Cooperative Fishery Research Unit, Logan.
C. R. Berry, Jr., and R. Pimentel.
Transactions of the American Fisheries Society, Vol. 114, No. 3, p 397-402, May, 1985. 1 Fig, 2 Tab, 40 Ref.

Descriptors: *Colorado River, *Fish, *Fish behavior, *Fish swimming ability, Entrainment, Fish physiology, Squawfish, Chubs, Animal behavior, Water temperature.

A stamina tunnel was used to determine the prolonged swimming performance of age-0 humpback chubs (Gila cypha), bonytail chubs (G. elegans), and Colorado squawfish (Ptychocheilus lucius) and of subadult Colorado squawfish. The 'fatigue velocity' in body lengths per second at which 50% of the test fish were fatigued (FV50) was determined at 14, 20, and 26 C. The range of FV50 values for the three fishes (average total length in parentheses) were: humpback chubs (95 mm), 4.4-5.7: bonytail chubs (99 mm), 4.7-5.8; small Colorado squawfish (104 mm), 4.0-4.5; large Colorado squawfish (432 mm), 2.0-2.3. Absolute speed of large Colorado squawfish was about 2.4 times that of small Colorado squawfish. Swimming ability of the subyearlings increased with increased water temperature. These rare fish had prolonged-swimming abilities similar to other fish species. (Author's abstract)
W86-01151

MORTALITY OF JUVENILE AMERICAN SHAD AND BLUEBACK HERRING PASSED THROUGH A LOW-HEAD KAPLAN HYDROELECTRIC TURBINE,
Massachusetts Cooperative Fishery Research Unit, Amherst.
R. E. Taylor, and B. Kynard.
Transactions of the American Fisheries Society, Vol. 114, No. 3, p 430-435, May, 1985. 1 Fig, 2 Tab, 15 Ref.

Descriptors: *Turbines, *Mortality, *Shad, *Herring, Fish migration, Hydroelectric plants, Lowhead hydropower, Cavitation, Controlled surface sillage, Fish behavior.

The objectives of this study were to determine the immediate turbine induced mortality of juveniles at a lowhead hydropower facility during natural downstream migration and to test for differences in fish mortality associated with three levels of electrical generation. Turbine induced mortality was estimated at 62% for the 16.5 MW mode of generation, and 82% for both the 12.0 MW and 5.5 MW modes. There were no significant differences in the recovery rates for prekilled fish or control fish among treatments, but there were for test fish. Recovery of test fish increased with electrical output of the turbine. Cavitation is thought to be the most important source of mortality to juvenile fish passed through Kaplan turbines. Whether or not controlled surface sillage at a dam would be an effective method of bypassing juveniles around the turbines is not known but preliminary indications are encouraging. Also, the peak in daily movement of juvenile American shad is between 1800 and 2000 hr EST during outmigration. This could minimize mortality because the turbines are typically under moderate to heavy loads at night and are usually running at the 26.5 MW generation mode. (Baker-IVI)

SIMULATING FISH REDISTRIBUTION IN THE LG-2 RESERVOIR AFTER FLOODING,
Sherbrooke Univ. (Quebec). Dept. of Chemical Engineering.
K. A. Morrison, N. Therien, and B. Coupal.
Ecological Modelling, Vol. 28, No. 1/2, p 97-111, May, 1985. 7 Fig, 2 Tab, 15 Ref.

Descriptors: *Fish populations, *Model studies, *Reservoirs, *Fish behavior, *Reservoir fisheries, *Flooding, *LG-2 Reservoir, *La Grande Hydroelectric Complex, *Quebec, Reservoir operation, Fisheries management, Species distribution, Fish migration, Populations, Animal behavior.

The changes that occur to fish movements and distributions as a result of the flooding of a large reservoir are not well known. Some of the mechanisms causing such changes can be identified. A model was developed of the movements of fish populations in the LG-2 reservoir of the La Grande Hydroelectric Complex in Quebec over the 2 years following innundation. The only processes examined by the model are dilution and depth changes. The purpose of the model is to provide approximate estimates of what would occur to observed fish catches if these were the only processes going on; the model thus provides a null hypothesis against which experimental data can be compared to evaluate the importance of the other processes affecting fish distributions during and immediately after flooding. Two species are examined, the walleye (Stizostedion vitreum) and the longnose sucker (Catostomus catostomus), and results were compared to observations. The only processes examined by the model are dilution and depth changes. Population distributions and water depth were plotted using a three-dimensional graphing system. The model predictions are fairly close after the 1st year but diverge from observations at several stations after the 2nd year. This divergence may be due to the adaptation of the populations to new spawning areas, a factor not yet considered in the model. One area requiring more research is habitat preference of deeper-water species. The model is also simplistic in that it does not allow for seasonal changes in habitat preferences. Movements to spawning areas fall within this set of factors. The inclusion of these effects will allow the model to make more realistic projections into the future, and will allow some examinations of the influences of the managed bays on fish distributions. Seasonal Changes in the Generic Composition of Heterotrophic Bacteria in Seawater of Kagoshima Bay (in Japanese),
W86-01148 5B

BACTERIAL ANALYSIS
Enumerating Injured Coliforms in Drinking Water,
W86-01265 5A

Test Instructions for Measuring the Microbial Metabolic Activity in Water Samples,
W86-01302 5A

BACTERIAL LEACHING
Decontaminating Biological Sludge for Agricultural Use,
W86-01183 5D

BACTERIAL PHYSIOLOGY
Test Instructions for Measuring the Microbial Metabolic Activity in Water Samples,
W86-01302 5A

BACTERIOPHAGE
F Specific RNA Bacteriophages in Sewage: Methodology and Occurrence,
W86-01189 5A

BAKU
Hygienic Evaluation of Bentonitic Clays and Filtrating Material from Azerbaijhan Deposits. 2nd Communication: Toxicologic and Hygienic Studies of the Bentonitic Clays from Agburun Deposits (Gigienicheskaya Otsenka Bentonitovykh Glini Fil'truyushchego Materiala Azerbaidzhandskogo Mestorozhdeniya),
W86-01257 5F

BALTIC SEA
Comparison of Planktonic and Periphytic Microalgal Parameters as Indicators of Eutrophication in a Baltic Archipelago: Annual Succession of Community Parameters,
W86-00931 7B

Nitrogen Transformations in the Baltic Proper: Denitrification Counteracts Eutrophication,
W86-01278 5B

BANGKOK
Simulated Salt-Water Movement in the Nakhon Luang Aquifer, Bangkok, Thailand,
W86-01313 2F

BANGLADESH
Farakka - The Largest Barrage in the World - an Engineering Marvel,
W86-01211 8A

BARDENPHO PROCESS
Design and Operation of Bardenpho Plants in an African Country,
W86-01015 5D

BARIUM
Arsenic, Barium, Germanium, Tin, Dimethylsulfide and Nutrient Biogeochemistry in Charlotte Harbor, Florida, A Phosphorus-Enriched Estuary,
W86-01113 5B

BASS
Modelling Kepone in the Striped Bass Food Chain of the James River Estuary,
W86-01116 5B

Plasma Osmotic and Electrolyte Concentrations of Largemouth Bass from Some Acidic Florida Lakes,
W86-01154 5C

Growth and Feeding Behaviour Responses of Largemouth Bass (Micropterus salmoides) Exposed to PCP,
W86-01157 5C

BAYS
Phytoplankton Dynamics in a Hypertrophic Brackish-Water Bay,
W86-00932 5C

Sea-Surface Microlayer Metals Enrichments in an Urban and Rural Bay,
W86-01114 5B

Hydrology and Changes in the Nutrients and Phytoplankton Levels in Goat Island Bay, Northern New Zealand,
W86-01127 2L

BEAM MODE BUCKLING
Model for Beam-Mode Buckling of Buried Pipelines,
W86-01079 8A

BED LOAD
Bed Material Movement in Hyperconcentrated Flow,
W86-01050 2J

BENTHAL DEPOSITS
Stabilization of Organic Carbon and Nitrogen in Consolidating Benthal Deposits,
W86-01232 5D

BENTHIC ENVIRONMENT
Analysis of the Benthic Macroinvertebrate Community of a Fluctuating River-Reservoir Zone in Middle Tennessee,
W86-01317 6G

BENTHIOCARB
Effects of Benthiocarb Herbicide on Growth of Planktonic Organisms, Chlorella saccharophila and Brachionus plicatilis,
W86-01146 5C

BENTHOS
Benthic Faunas and Food Resources of Insects in Small New Zealand Streams Subjected to Different Forestry Practices,
W86-00927 4C

Pattern Recognition Techniques to Determine Benthic Invertebrate Trophic and Community Responses to Industrial Input,
W86-00934 5C

Evaluation of the Use of Artificial Substrates in Sampling the Invertebrate Fauna of Sewage Fungus Slimes in Irish Rivers,
W86-00936 7B

Energy Extraction From Lake Sediments with Heat Exchangers. Effects on Water Quality, Sediment, Bottom Fauna, and Fish,
W86-00938 6G

Influence of the Sewage Treatment Plant Effluents on the Structure of the Benthic Communities of Lake of Geneva,
W86-00949 5C

Composition and Productivity of the Benthic Macroinvertebrate Community of a Subtropical Reservoir,
W86-01130 2H

Recovery of a Stream Invertebrate Community from a Flash Flood in Tesuque Creek, New Mexico,
W86-01170 2H

BENTONITE
Hygienic Evaluation of Bentonitic Clays and Filtrating Material from Azerbaijhan Deposits. 2nd Communication: Toxicologic and Hygienic Studies of the Bentonitic Clays from Agburun Deposits (Gigienicheskaya Otsenka Bentonitovykh Glini Fil'truyushchego Materiala Azerbaidzhandskogo Mestorozhdeniya),
W86-01257 5F

BENZOPYRENE
Leachability of Carbon-14-Labelled 3,4-Benzopyrene from Coal Ash into Aqueous Systems,
W86-00997 5B

BERLIN
Photosynthetic Activity of Dominant Algal Species in Eutrophic Shallow Lake (Grosser Muggelsee, Berlin) Investigated by Microautoradiography,
W86-01131 2H

Oxygen Balances in the Teltow-Canal - With Special Regard to Heat Discharge from Lichterfelde Power Plant (Berlin, West) (Sauerstoffbilanzen im Teltowkanal - insbesondere unter dem Einfluss der Abwarmeeinleitung aus dem Kraftwerk Lichterfelde (Berlin, West)),
W86-01141 5B

BERSBO
Biosphere Levels of Cadmium, Zinc and Copper Around an Old Swedish Copper Mine,
W86-01280 5C

BEST MANAGEMENT PRACTICES
Modeling Water Quality and the Effects of Agricultural Best Management Practices in the Iowa River Basin,
W86-01248 5G

BIENNE RIVER
Use of Aquatic Bryophytes to Monitor Heavy Metals Pollution of Freshwaters as Illustrated by Case Studies,
W86-00962 7B

BIGHORN BASIN
Gradient Controlled Caves, Trapper-Medicine Lodge Area, Bighorn Basin, Wyoming,
W86-01305 2F

BIOACCUMULATION
Characteristic Distribution of Chironomids in the Rivers Polluted with Heavy Metals,
W86-00954 5C

Cadmium and Chromium in the Waters, Sediments and Biota of the Val Parma Running Water Ecosystem,
W86-00957 5B

BIOASSAY
Role of the Daphnia Bioassay in the Assessment of the Quality of Effluent Discharges,
W86-01024 5A

Cytotoxicity/Genotoxicity: The Application of Cell Culture Techniques to the Measurement of Marine Sediment Pollution,
W86-01158 5C

BIOASSAYS
Application of Acute Bioassays in Evaluating the Treatment of Coal Liquefaction Wastewaters,
W86-01284 5D

Invertebrate Bioassays with North Sea Water Samples. I. Structural Effects on Embryos and Larvae of Serpulids, Oysters and Sea Urchins,
W86-01318 5A

BIOCONCENTRATION
Uptake, Biotransformation, and Elimination of Rotenone by Bluegills (Lepomis macrochirus),
W86-01159 5C

BIODEGRADATION
Dibutylphthalate Degradation in Estuarine and Freshwater Sites,
W86-00994 5B

BIOGEOCHEMISTRY
Arsenic, Barium, Germanium, Tin, Dimethylsulfide and Nutrient Biogeochemistry in Charlotte Harbor, Florida, A Phosphorus-Enriched Estuary,
W86-01113 5B

BIOINDICATORS
Comparison of Planktonic and Periphytic Microalgal Parameters as Indicators of Eutrophication in a Baltic Archipelago: Annual Succession of Community Parameters,
W86-00931 7B

Using Several Indices for Biological Assessment of Water Quality in Running Water,
W86-00942 5A

Use of Bacteria Attached to Submerged Macrophytes and Glass Slides as Indicators of an Increasing Water Pollution,
W86-00943 7B

Characterization of Differently Polluted Ponds by Submerged Macrophytes and Various Denitrifying Bacteria,
W86-00944 5A

Diatom Flora of the Llobregat River and its Relation to Water Quality,
W86-00950 2H

Use of Aquatic Bryophytes to Monitor Heavy Metals Pollution of Freshwaters as Illustrated by Case Studies,
W86-00962 7B

Use of Limnocorrals for Pesticide Toxicity Studies: Effect on Zooplankton Composition and Dynamics,

CYCLOTRIMETHYLENE-TRINITRAMINE
High Temperature Treatment of Trinitrotoluene (TNT) and Cyclotrimethylene-Trinitramine (RDX) with Ozone and Ultrasound,
W86-01271 5D

CYTOTOXICITY
Cytotoxicity/Genotoxicity: The Application of Cell Culture Techniques to the Measurement of Marine Sediment Pollution,
W86-01158 5C

CZECHOSLOVAKIA
Elimination of Nutrients in the Rozkos-Reservoir,
W86-01002 5B

Humic Acids in the Inflows to the Flaje Reservoir after Deforestation of its Watershed,
W86-01010 6G

DAM CONSTRUCTION
Earthworks at the Inguri Hydroelectric Station Construction Site,
W86-00984 8D

Damming the Volga Channel at the Cheboksary Hydroelectric Station,
W86-00987 8B

Reconstruction of a Dam Water Intake Under Conditions of Continuous Operation of the Reservoir,
W86-00990 8A

DAM EFFECTS
Effects of Impoundment and Drawdown on the Fish Community of a South American River,
W86-00978 6G

DAM FOUNDATION
Simplified Earthquake Analysis of Concrete Gravity Dams: Separate Hydrodynamic and Foundation Interaction Effects,
W86-01080 8A

DAM FOUNDATIONS
Elastic Deformation of the Foundation of the Bratsk Concrete Dam,
W86-00991 8E

Simplified Earthquake Analysis of Concrete Gravity Dams: Combined Hydrodynamic and Foundation Interaction Effects,
W86-01081 8A

DAM FOUNDATIONS

Investigation of Dam Sites: Modern Practices,
W86-01210 8E

DAM STABILITY
Stress-Strain State of Earth Dams on Undermined Territories,
W86-00988 8E

DANUBE RIVER
Water Plants, an Indicator for Radioactive Contamination (Wasserpflanzen, ein Indikator for Radioaktive Veruneinigungen),
W86-00971 5A

DAPHNIA
Role of the Daphnia Bioassay in the Assessment of the Quality of Effluent Discharges,
W86-01024 5A

Quantitative Structure Activity Relationships and Mixture Toxicity Studies of Alcohols and Chlorohydrocarbons: Effects on Growth of Daphnia magna,
W86-01160 5C

DARLING RIVER
Zooplankton of the Darling River System, Australia,
W86-00925 2H

DATA COLLECTIONS
Compilation of Alluvial Channel Data,
W86-01097 2J

DECISION MAKING
Multi-Objective Decision-Making in Waste Disposal Planning,
W86-01044 5E

DEFORESTATION
Humic Acids in the Inflows to the Flaje Reservoir after Deforestation of its Watershed,
W86-01010 6G

DEFORMATION
Generalized Relations Between Static and Dynamic Indices of Rock Deformability,
W86-00985 8E

Elastic Deformation of the Foundation of the Bratsk Concrete Dam,
W86-00991 8E

DEGRADATION
Environmental Behavior of Fluorotensides. Part 2. Investigation on the Biochemical Degradability (Zum Umweltverhalten von Fluortensiden. Teil 2. Untersuchung der Biochemischen Abbaubarkiet),
W86-01007 5B

DELAWARE BAY
Arsenic Incorporation in a Salt Marsh Ecosystem,
W86-01118 5B

DENITRIFICATION
Nitrogen Transformations in the Baltic Proper: Denitrification Counteracts Eutrophication,
W86-01278 5B

DENMARK
Modelling of Oxygen Depletion in Coastal Waters,
W86-01235 5C

DESERTS
Dissolved Inorganic Phosphorus in Streams of the Indian Arid Zone,
W86-01292 2J

DESIGN CRITERIA
Ways of Using the Bearing Properties of a Rock Mass When Designing Underground Hydraulic Structures,
W86-00982 8E

Provision of Stability of Unlined Canals,
W86-00992 8D

Tests on a French Adjustable Two-Stage Pump-Turbine,
W86-01274 8C

Design and Operation of a Fuse-Plug Spillway in Swaziland,
W86-01275 8A

DESTRATIFICATION
Effects of Wind, Phytoplankton and Density Discontinuities upon Ammonia Distributions in Liverpool Bay,
W86-01120 2L

DETERGENTS
Treatment of Industrial Wastewaters Carrying Oily Emulsions, Surfactans and Sulphates,
W86-01014 5D

Detergents for Reservoirs and Colony Increases in Potable Water (Reinigungsmittel fur Behalter und Koloniezahl-erhohungen im Trinkwasser),
W86-01140 5F

DHORA RESERVOIR COMMAND AREA
Uncertainty Analysis of Water Resource Use in Dhora Reservoir Command Area,
W86-01220 3F

DIATOMS
Diatom Communities of the Polluted Rivers of Central Poland (Les Communautes des Diatomees dans les Rivieres Polluees de la Pologne Centrale),
W86-00947 5C

Diatom Flora of the Llobregat River and its Relation to Water Quality,
W86-00950 2H

Palaeolimnological Record of Human Disturbance from Harvey's Lake, Vermont: Geochemistry, Pigments and Diatoms,
W86-01122 2H

DIBUTYLPHTHALATE
Dibutylphthalate Degradation in Estuarine and Freshwater Sites,
W86-00994 5B

DICHLOROPHENOXYACETATE
Elimination of the Water Pollutant 2,4-D through Adsorption by Aluminum Oxide (Zur Elimination des Wasserschadstoffes 2,4-D durch Adsorption an Aluminiumoxid),
W86-01005 5F

DIFFUSION
Assessment of the Significant Physicochemical Interactions Involved in Pesticide Diffusion within a Pesticide-Sediment-Water System,
W86-00995 5B

DIFFUSION COEFFICIENTS
Diffusion Coefficient Evaluated From the Distribution of Nonconservative Material (in Japanese),
W86-01143 5B

DIMETHYLSULFIDE
Arsenic, Barium, Germanium, Tin, Dimethylsulfide and Nutrient Biogeochemistry in Charlotte Harbor, Florida, A Phosphorus-Enriched Estuary,
W86-01113 5B

DISINFECTION
Disinfection of Circulating Water Systems by Ultraviolet Light and Halogenation,
W86-01059 5F

Use of Peracetic Acid in Operational Sewage Sludge Disposal to Pasture,
W86-01175 5D

Sludge Stabilisation and Disinfection by Means of Autothermal Aerobic Digestion with Oxygen,
W86-01182 5D

Disinfection of Drinking Water Rich in
with Chlorine and Chlorine Dioxide
Minimizing the Formation of Undesir
Products,
W86-01186

Influence of Bubble Sizes on Ozone S
Utilization and Disinfection,

FLOWMETERS
Laboratory Investigation and Analysis of a Ground-Water Flowmeter,
W86-01310 2F

FLUID MECHANICS
Head-Discharge Relation for Vortex Shaft,
W86-01053 8B

FLUORIMETRY
Determination of Selenium in Sewage Sludge Using an Acid-Digestion Bomb and Fluorimetry,
W86-01026 5A

FLUOROTENSIDES
Environmental Behavior of Fluorotensides. Part 2. Investigation on the Biochemical Degradability (Zum Umweltverhalten von Fluortensiden. Teil 2. Untersuchung der Biochemischen Abbaubarkiet),
W86-01007 5B

FLUSHING
Restoration of Lake Veluwe, The Netherlands, by Reduction of Phosphorus Loading and Flushing,
W86-01198 5G

FLY ASH
Copper(II) Removal from Aqueous Solutions by Fly Ash,
W86-01062 5D

FODDER
Effects of Irrigation and Soil Management for Fodder Crops on Root Zone Conditions in a Red-brown Earth,
W86-01032 3F

FONTINALIS
Influence of Zinc and Lead Compounds in Water on the Assimilation of Fontinalis antipyretica (Zum Einfluss von Ruckstanden von Zink- und Bleiverbindungen im Wasser auf die Assimilation von Fontinalis antipyretica),
W86-01008 5C

FOOD CHAIN
Modelling Kepone in the Striped Bass Food Chain of the James River Estuary,
W86-01116 5B

FOOD CHAINS
Qualitative Analysis of the Pelagic Foodwebs of Three Acid-Impacted Lakes in Nova Scotia, Canada,
W86-01129 2H

FOOD PROCESSING INDUSTRY
Anaerobic Treatment of Waste Waters in the Beet Sugar Industry,
W86-01020 5D

FOODS
Benthic Faunas and Food Resources of Insects in Small New Zealand Streams Subjected to Different Forestry Practices,
W86-00927 4C

FORECASTING
Model for Forecasting Acute Toxicity of River Water for Fish (Modele de Prevision de la Toxicite aigue des eaux de Rivieres Pour le Poisson),
W86-00968 5C

FOREST MANAGEMENT
Benthic Faunas and Food Resources of Insects in Small New Zealand Streams Subjected to Different Forestry Practices,
W86-00927 4C

FORT COLLINS
Stormwater Management Emphasizes Soft Improvements,
W86-01315 4A

FOUNDATION FAILURE
Stress-Strain State of Earth Dams on Undermined Territories,
W86-00988 8E

FRANCE
Use of Aquatic Bryophytes to Monitor Heavy Metals Pollution of Freshwaters as Illustrated by Case Studies,
W86-00962 7B

Radionuclide Content Measurement and Interpretation in Fish from the Upper Rhone River in France (Mesure et Interpretation des Teneurs en Radionucleides de Poissons du Haut-Rhone Francais),
W86-00970 5A

FRANCIS TURBINES
Advantages of Turgo-Impulse Turbines in Micro-Hydel Units,
W86-01204 8C

FREE OVER-FALL SPILLWAYS
Hydraulic Design of Free Over-Fall Spillway,
W86-01208 8A

FROUDE NUMBER
Subdivision Froude Number,
W86-01094 2E

FUEL OIL
Responses of Benthic Meiofauna to Long-Term, Low-Level Additions of No. 2 Fuel Oil,
W86-01124 5C

FULVIC ACID
Effects of Water Quality on Microporous Filter Methods for Enteric Virus Concentration,
W86-01191 5A

FUSE-PLUG SPILLWAYS
Design and Operation of a Fuse-Plug Spillway in Swaziland,
W86-01275 8A

GANGA RIVER
Farakka - The Largest Barrage in the World - an Engineering Marvel,
W86-01211 8A

GENOTOXICITY
Cytotoxicity/Genotoxicity: The Application of Cell Culture Techniques to the Measurement of Marine Sediment Pollution,
W86-01158 5C

Genotoxic Activity of Particulate Material in Petroleum Refinery Effluents,
W86-01283 5C

GEOCHEMISTRY
Palaeolimnological Record of Human Disturbance from Harvey's Lake, Vermont: Geochemistry, Pigments and Diatoms,
W86-01122 2H

GEOHYDROLOGY
Comparison of Gaussian Conditional Mean and Kriging Estimation in the Geostatistical Solution of the Inverse Problem,
W86-01074 2F

Gradient Controlled Caves, Trapper-Medicine Lodge Area, Bighorn Basin, Wyoming,
W86-01305 2F

GEOLOGIC FRACTURES
Practical Method for Modeling Fluid and Heat Flow in Fractured Porous Media,
W86-01138 2F

GEOSTATISTICAL METHODS
Comparison of Gaussian Conditional Mean and Kriging Estimation in the Geostatistical Solution of the Inverse Problem,
W86-01074 2F

GEOTHERMAL RESOURCES
Quantitative Analysis of the Lassen Hydrothermal System, North Central California,
W86-01077 2F

GERMANIUM
Arsenic, Barium, Germanium, Tin, Dimethylsulfide and Nutrient Biogeochemistry in Charlotte Harbor, Florida, A Phosphorus-Enriched Estuary,
W86-01113 5B

GERMANY (DEMOCRATIC REPUBLIC)
Photosynthetic Activity of Dominant Algal Species in Eutrophic Shallow Lake (Grosser Muggelsee, Berlin) Investigated by Microau
graphy,
W86-01131

GERMANY (FEDERAL REPUBLIC)
Use of Bacteria Attached to Submerged
phytes and Glass Slides as Indicators o
creasing Water Pollution,
W86-00943

Characterization of Differently Pollute
by Submerged Macrophytes and Vario
trifying Bacteria,
W86-00944

Restoration of a Small Lake by Combi
chanical and Biological Methods,
W86-00946

Water Plants, an Indicator for Radioact
tamination (Wasserpflanzen, ein Indik
Radioaktive Veruneinigungen),
W86-00971

Oxygen Balances in the Teltow-Canal
Special Regard to Heat Discharge from
felde Power Plant (Berlin, West) (Sau
lanzen im Teltowkanal - insbesondere u
Einfluss der Abwarmeeinleitung a
Kraftwerk Lichterfelde (Berlin, West)),
W86-01141

Application of Information about Con
in the Computing of Ion Concentratio
trated by Certain Surface Waters Sit
Lower Saxony,
W86-01224

GETALSUD DAM
Management of Mud, Problematic in t
dations of Chandan and Getalsud Earth
Bihar (India),
W86-01213

GILLS
Zinc Induced Lesions in the Gills of
daniconius neilgeriensis (Hamilton),
W86-01004

GOAT ISLAND BAY
Hydrology and Changes in the Nutri
Phytoplankton Levels in Goat Isla
Northern New Zealand,
W86-01127

GRANULAR ACTIVATED CARBON
Purification of Polluted Source Wa
Ozonation and Biological Activated Ca
W86-01269

GRASSLANDS
Controlling Metal Uptake from Hea
Sludge Applied to Grasslands,
W86-01185

GRAVITY DAMS
Simplified Earthquake Analysis of
Gravity Dams: Separate Hydrodyna
Foundation Interaction Effects,
W86-01080

Simplified Earthquake Analysis of
Gravity Dams: Combined Hydrodyn
Foundation Interaction Effects,
W86-01081

Three Dimensional Finite Element Stre
sis of Gravity Dams,
W86-01219

GRAYLINGS
Grayling (Thymallus thymallus (L.)
Lower Part of the Rautalampi Wa
Finnish Lake District,
W86-00974

ASE
eam Modeling of Nonconvetional Water
ality Parameters: Phenol, Cyanide, Ammonia,
and Grease,
6-01234 5B

AT LAKES
ects of Entrainment on Phytoplankton Pri-
y Production at Four Thermal Electric Gen-
ing Stations on the Laurentian Great Lakes,
6-01132 5C

chine Classification of Freshwater Ice Types
n Landsat-1 Digital Data Using Ice Albedos
Training Sets,
6-01288 2C

AT OUSE CHALK
delling Non-Point Sources of Nitrate Pollu-
of Groundwater in the Great Ouse Chalk,
.,
6-01294 5B

N BAY
chine Classification of Freshwater Ice Types
n Landsat-1 Digital Data Using Ice Albedos
Training Sets,
6-01288 2C

NDWATER
iocarbon Dating of Groundwater in Tertiary
ments of the Eastern Murray Basin,
6-01036 2F

tification of Parameter Structure in Ground-
r Inverse Problem,
6-01078 2F

NDWATER BUDGET
ntorying Ground Water in Crystalline
ks of Piedmont Region,
6-01104 2F

NDWATER CONTAMINATION
elling Non-Point Sources of Nitrate Pollu-
of Groundwater in the Great Ouse Chalk,
,
6-01294 5B

ity of Water in an Aquifer and its Manifesta-
In Pumping Wells,
6-01299 2F

NDWATER EXTRACTION
rology of Bank Groundwater Withdrawals
e Netherlands,
6-01298 4B

NDWATER FLOW
pretation of Dug Well Performance Using a
al Model,
6-01306 2F

NDWATER LEVEL
onse of Groundwater Levels to Rainfall
to Leaf Growth of Farm Plantations Near
Seeps,
6-01290 2F

NDWATER MANAGEMENT
e Computational Experiences Using Embed-
Technique for Ground-Water Management,
6-01307 2F

NDWATER MOVEMENT
tical Method for Modeling Fluid and Heat
in Fractured Porous Media,
6-01138 2F

in a Limestone Aquifer as Determined
Water Tracing and Water Levels in Wells,
6-01296 2F

rology of Bank Groundwater Withdrawals
e Netherlands,
6-01298 4B

Gradient Controlled Caves, Trapper-Medicine Lodge Area, Bighorn Basin, Wyoming,
W86-01305 2F

Laboratory Investigation and Analysis of a Ground-Water Flowmeter,
W86-01310 2F

Simulated Salt-Water Movement in the Nakhon Luang Aquifer, Bangkok, Thailand,
W86-01313 2F

GROUNDWATER POLLUTION
Groundwater Pollution Hazard in the Cape Flats,
W86-01017 5G

Ground-Water Contamination in Silicon Valley,
W86-01108 5B

Considerations on Water, Oil and Air in Porous Media,
W86-01176 5B

Leachate Attenuation in the Unsaturated Zone Beneath Landfills: Instrumentation and Monitoring of a Site in Southern England,
W86-01177 5A

Factors Controlling the Survival of Viruses in Groundwater,
W86-01192 5B

Movement of Volatile Organics Through a Fractured Rock Aquifer,
W86-01311 5B

County Restores Groundwater Aquifer,
W86-01314 5G

GROUNDWATER RECHARGE
Hydrology of Bank Groundwater Withdrawals in the Netherlands,
W86-01298 4B

GROUNDWATER RESERVOIRS
Ground-Water Reservoir Operation for Drought Management,
W86-01105 4B

GROWTH
Effects of Benthiocarb Herbicide on Growth of Planktonic Organisms, Chlorella saccharophila and Brachionus plicatilis,
W86-01146 5C

Growth and Feeding Behaviour Responses of Largemouth Bass (Micropterus salmoides) Exposed to PCP,
W86-01157 5C

Quantitative Structure Activity Relationships and Mixture Toxicity Studies of Alcohols and Chlorohydrocarbons: Effects on Growth of Daphnia magna,
W86-01160 5C

Growth Rate of Yearling Colorado Squawfish at Different Water Temperatures,
W86-01169 6G

Response of Groundwater Levels to Rainfall and to Leaf Growth of Farm Plantations Near Salt Seeps,
W86-01290 2F

GRUA
Cr6+ Influence upon Ephemeroptera Larvae in a Pre-Alpine Torrent,
W86-00956 5C

GULF OF CARPENTARIA
Short-Term and Long-Term Influences on the Immigration of Postlarval Banana Prawns Penaeus merguiensis, Into a Mangrove Estuary of the Gulf of Carpentaria, Australia,
W86-01125 2L

GUMA DAM
Some Physical and Chemical Properties of Water from an Undisturbed Tropical Catchment Area (Guma Dam, Sierra Leone),
W86-01134 2H

GUNDREMMING
Water Plants, an Indicator for Radioactive Contamination (Wasserpflanzen, ein Indikator for Radioaktive Veruneinigungen),
W86-00971 5A

GURGLER ACHE
Influence of Organic Pollution on the Macroinvertebrate Communities of Mountain Streams,
W86-00948 5C

HALOGENATED HYDROCARBONS
Mutagenicity and Organic Halogen Determination in Body Fluids and Tissues of Rats Treated with Drinking Water and Pulp Mill Bleachery Effluent Concentrates,
W86-00993 5C

Preliminary Study of the Efficiency and Mechanism of THM Removal in the Ozonation and BAC Process,
W86-01270 5F

HAN RIVER
Water Quality Modelling of the Lower Han River, Korea,

KURA RIVER
Hygienic Evaluation of Bentonitic Clays and Filtrating Material from Azerbaijhan Deposits. 2nd Communication: Toxicologic and Hygienic Studies of the Bentonitic Clays from Agburun Deposits (Gigienicheskaya Otsenka Bentonitovykh Glini Fil'truyushchego Materiala Azerbaidzhandskogo Mestorozhdeniya),
W86-01257 5F

KUZINSK
Structural Features of the Grey-Brownish Black Sandy Soils of Apsheron and Their Alteration Following Application of Water Pipe Sludge from Kuzinsk (Mikromorfologicheskie Osobennosti Sero-Burykh Peschanykh Pochv Apsherona i ikh Izmenenie Pri Vnesenii Kurinskogo Vodoprovodnogo Osadka),
W86-01256 5E

LA GRANDE HYDROELECTRIC COMPLEX
Simulating Fish Redistribution in the LG-2 Reservoir After Flooding,
W86-01166 8I

LAGO DO REI
Fishing and Hydrologie in the Central Amazon (Peche et Hydrologie en Amazonie Centrale),
W86-00977 2H

LAHONTAN RESERVOIR
Species Composition and Seasonal Succession of the Zooplankton Community of Eutrophic Lahontan Reservoir, Nevada,
W86-01168 2H

LAKE ANKETJARN
Lake Anketjarn, A Non-Acidified Lake in an Acidified Region,
W86-01165 2H

LAKE EYRE CATCHMENT
Estimated Store of Soluble Salts in the Lake Eyre Catchment in Queensland and their Possible Transport in Streamflow to the Lake,
W86-01031 2A

LAKE GENEVA
Influence of the Sewage Treatment Plant Effluents on the Structure of the Benthic Communities of Lake of Geneva,
W86-00949 5C

LAKE HOLMSJON
Stratification and Primary Production in a Small Brackish Lake Studied by Close-Interval Siphon Sampling,
W86-00930 2H

LAKE KHURPATAL
Compositional and Structural Analysis of Phytoplankton in Lake Khurpatal, (U.P.), India,
W86-01133 2H

LAKE MICHIGAN
Machine Classification of Freshwater Ice Types from Landsat-1 Digital Data Using Ice Albedos as Training Sets,
W86-01288 2C

LAKE OKEECHOBEE
Water Quality and Regional Water Supply Planning,
W86-01101 4A

LAKE ONTARIO
Assessment of Ecological Changes During the Recent History of Lake Ontario Based on Siliceous Algal Microfossils Preserved in the Sediments,
W86-01110 2H

LAKE ORTA
Sediment as a Record of Copper Pollution in Lake Orta,
W86-00958 5B

LAKE PAIJANNE
Distribution and Decomposition of Lignosulphonates in Lake Paijanne, Central Finland,
W86-00939 5B

LAKE RESTORATION
Restoration of a Small Lake by Combined Mechanical and Biological Methods,
W86-00946 5G

Restoration of Lake Veluwe, The Netherlands, by Reduction of Phosphorus Loading and Flushing,
W86-01198 5G

LAKE SEDIMENTS
Energy Extraction From Lake Sediments with Heat Exchangers. Effects on Water Quality, Sediment, Bottom Fauna, and Fish,
W86-00938 6G

Mercury in Sediment in Swedish Forest Lakes,
W86-00952 5B

Sediment as a Record of Copper Pollution in Lake Orta,
W86-00958 5B

Source of Hydrogen Sulfide in Anoxic Sediment,
W86-01063 2H

Palaeolimnological Record of Human ance from Harvey's Lake, Vermont: G try, Pigments and Diatoms,
W86-01122

LAKE VELUWE
Restoration of Lake Veluwe, The Ne by Reduction of Phosphorus Loading a ing,
W86-01198

LAKE ZEMBORZYCE
Chemical Composition of Bottom Sedi Phytoplankton in the Man-made Lake zyce near Lublin,
W86-01319

LAKES
Grayling (Thymallus thymallus (L. Lower Part of the Rautalampi Wa Finnish Lake District,
W86-00974

Some Observations on the Oxygen Ch Lake Covered with Pistia stratiotes L.,
W86-01068

Qualitative Analysis of the Pelagic Fo Three Acid-Impacted Lakes in No Canada,
W86-01129

Changes in the Pleustic Macrophyte F Small Finnish Lakes in 30 Years,
W86-01156

Factor Interaction Influencing the D of the Freshwater 'Shrimp' Gammarus
W86-01162

Colloidal Stability of Particles in La urement and Significance,
W86-01194

Quantification of Wind Induced Resu a Shallow Lake,
W86-01230

LAND APPLICATION
Structural Features of the Grey-Brow Sandy Soils of Apsheron and Their Following Application of Water Pi from Kuzinsk (Mikromorfologicheski nosti Sero-Burykh Peschanykh Poch ona i ikh Izmenenie Pri Vnesenii K Vodoprovodnogo Osadka),
W86-01256

LAND DISPOSAL
Controlling Metal Uptake from He Sludge Applied to Grasslands,
W86-01185

Estimating Vertical Soil Moisture Land Treatment Site,
W86-01312

LAND USE
Surface Water Quality in Relation to Land Use and Discharge in a Rural Area,
W86-01249

LANDFILL LEACHATES
Leachate Treatment with Nitrificati monia,
W86-01065

LANDFILLS
Gas-chromatographic Determinatio Volatile Fatty Acids (C2 to C6) in Water of Household Refuse Dump (Die Gaschromatographische Bestim Freien Fluchtigen Fettsauren (C2 - C erwasser von Hausmulldeponien),
W86-01001

achate Attenuation in the Unsaturated Zone
neath Landfills: Instrumentation and Monitor-
of a Site in Southern England,

s pauciflora in Summer Along an Eleva-
radient,
163 2D

l Responses and Water Relations of Eu-
s pauciflora in Summer Along an Eleva-
radient,
163 2D

Response of Groundwater Levels to Rainfall and to Leaf Growth of Farm Plantations Near Salt Seeps,
W86-01290 2F

LG-2 RESERVOIR
Simulating Fish Redistribution in the LG-2 Reservoir After Flooding,
W86-01166 8I

LICHTERFELDE POWER PLANT
Oxygen Balances in the Teltow-Canal - With Special Regard to Heat Discharge from Lichterfelde Power Plant (Berlin, West) (Sauerstoffbilanzen im Teltowkanal - insbesondere unter dem Einfluss der Abwarmeeinleitung aus dem Kraftwerk Lichterfelde (Berlin, West)),
W86-01141 5B

LIGNIN
Distribution and Decomposition of Lignosulphonates in Lake Paijanne, Central Finland,
W86-00939 5B

LIGNOSULFONATES
Distribution and Decomposition of Lignosulphonates in Lake Paijanne, Central Finland,
W86-00939 5B

LIMBURG
Biological Assessment of Water Quality in Running Water Using Macroinvertebrates: A Case Study for Limburg, The Netherlands,
W86-01227 5A

LIMESTONE
Flow in a Limestone Aquifer as Determined From Water Tracing and Water Levels in Wells,
W86-01296 2F

LIMNOCORRALS
Use of Limnocorrals for Pesticide Toxicity Studies: Effect on Zooplankton Composition and Dynamics,
W86-00964 5A

LIMNOLOGY
Limnology of a Naturally Acidic Tropical Water System in Australia; I. General Description and Wet Season Characteristics,
W86-00923 2H

Limnology of a Naturally Acidic Tropical Water System in Australia; II. Dry Season Characteristics,
W86-00924 2H

Limnology and Fisheries Management in Zimbabwe,
W86-00976 2H

LININGS
On-Site Tests of a New Type of Tunnel Lining at the Nurek Hydrostation Construction Site,
W86-00981 8F

Asphaltic Concrete Linings for Pumped-Storage Reservoirs,
W86-01273 8F

LIQUID SCINTILLATORS
Suitability of Different Counting Vials and Liquid Scintillators for Determining Tritium in Water (Die Eignung verschiedener Messflaschchen und Szintillatorflussigkeiten zur Bestimmung von Tritium in Wasser),
W86-01142 7B

LITTLE GRIZZLY CREEK
Multilevel Approach to the Assessment of Ecotoxicological Effects in a Heavy Metal Polluted Stream,
W86-00953 5C

LIVERPOOL BAY
Effects of Wind, Phytoplankton and Density Discontinuities upon Ammonia Distributions in Liverpool Bay,
W86-01120 2L

LIVINGSTON RESERVOIR
Composition and Productivity of the Benthic Macroinvertebrate Community of a Subtropical Reservoir,
W86-01130 2H

LLOBREGAT RIVER
Diatom Flora of the Llobregat River and its Relation to Water Quality,
W86-00950 2H

LONG ASHTON
Recent Changes in Summer Rainfall Values Measured at Long Ashton,
W86-01303 2B

LOW HEAD
Low Head Canal Power Development in Punjab,
W86-01221 6B

LOWER SAXONY
Application of Information about Conductivity in the Computing of Ion Concentrations, Illustrated by Certain Surface Waters Situated in Lower Saxony,
W86-01224 5A

LUNI RIVER BASIN
Dissolved Inorganic Phosphorus in Streams of the Indian Arid Zone,
W86-01292 2J

MACROINVERTEBRATES
Drift in Hawaiian Streams,
W86-00922 2H

Macroinvertebrate Community of Stones in an Australian Upland Stream,
W86-00926 2H

Influence of Organic Pollution on the Macroinvertebrate Communities of Mountain Streams,
W86-00948 5C

Effects of Acute Parathion Pollution on Macroinvertebrates in a Stream,
W86-00963 5C

Organization of Macroinvertebrate Communities in the Major Tributaries of the LaTrobe River, Victoria, Australia,
W86-01123 2H

MACROPHYTES
Microfauna Distribution in Shallow Macrophyte-Covered Basins,
W86-00951 5D

Changes in the Pleustic Macrophyte Flora of 54 Small Finnish Lakes in 30 Years,
W86-01156 2H

MAGALA RIVER
Limnology of a Naturally Acidic Tropical Water System in Australia; I. General Description and Wet Season Characteristics,
W86-00923 2H

MAGELA CREEK
Limnology of a Naturally Acidic Tropical Water System in Australia; II. Dry Season Characteristics,
W86-00924 2H

MAGNETITE
Removal of Pesticides in Water by Microbial Cells Adsorbed to Magnetite,
W86-01057 5F

MAHARASHTRA
Mechanisation vs. Manual Execution of River Valley Projects in Maharashtra,
W86-01215 6A

MAINTENANCE
Detergents for Reservoirs and Colony Increases in Potable Water (Reinigungsmittel fur Behalter und Koloniezahl-erhohungen im Trinkwasser),
W86-01140 5F

MANAGEMENT PLANNING
Tomorrow's Technology for Today's Problems,
W86-01261 8A

MANIPUR
Mechanized Tunnelling - a Landmark in Indian Tunnelling Practice,
W86-01216 8A

MANURE
Water Retention, Transmission and Contact Characteristics of Ludas Sand as Influenced by Farmyard Manure,
W86-01033 3F

MARINE ENVIRONMENT
Enhancement of Marine Primary Production by Nitrogen-Enriched Acid Rain,
W86-01172 5C

Marine Quality Standards: Their Derivation and Application in the United Kingdom,
W86-01252 5G

MARINE SEDIMENTS
Cytotoxicity/Genotoxicity: The Application of Cell Culture Techniques to the Measurement of Marine Sediment Pollution,
W86-01158 5C

MASS TRANSPORT MODELS
Calibration of a Mass Transport Model Using Environmental Tritium,
W86-01289 5B

MATHEMATICAL EQUATIONS
Body-Fitted Coordinates for Flow Under Sluice Gates,
W86-01046 8B

Sediment Transport under Ice Cover,
W86-01047 2J

When and Where to Put a Discharge in an Oscillatory Flow,
W86-01056 5B

Numerical Determination of Aquifer Constants,
W86-01096 2F

MATHEMATICAL MODELS
Assessment of the Significant Physicochemical Interactions Involved in Pesticide Diffusion within a Pesticide-Sediment-Water System,
W86-00995 5B

Mathematical Simulation of the Conversion and Transport of Nutrients in Drainage Areas - A Review of the Literature (Mathematische Simulation von Nahrstoffumwandlung und -transport in Einzugsgebieten-Literaturubersicht),
W86-00999 5B

Contribution to the Analytical Description of Transport Processes in the Aquifer at a Diffuse Substance Input (Beitrag zur analytischen Beschreibung von Transportprozessen im Grundwasserleiter bei diffusem Stoffeintrag),
W86-01012 5B

Fluid and Sediment Interaction Over a Plane Bed,
W86-01045 2J

Comparison of Gaussian Conditional Mean and Kriging Estimation in the Geostatistical Solution of the Inverse Problem,
W86-01074 2F

Comparison of Two River Diffuser Models,
W86-01093 8B

Modelling Kepone in the Striped Bass Food Chain of the James River Estuary,
W86-01116 5B

Stream Modeling of Nonconvetional Water Quality Parameters: Phenol, Cyanide, Ammonia, Oil and Grease,
W86-01234 5B

Role for a Simple Discrete-Time Model to Describe Dispersion in an Estuary,
W86-01237 2L

Modelling of the Coagulation-Adsorption Process in Treatment Systems,
W86-01245 5F

MAZAWA
Characteristic Distribution of Chironomids in the Rivers Polluted with Heavy Metals,
W86-00954 5C

MEANDERING STREAMS
Direct Measurements of Secondary Currents in a Meandering Sand-Bed River,
W86-01171 2E

MEASURING INSTRUMENTS
Suitability of Different Counting Vials and Liquid Scintillators for Determining Tritium in Water (Die Eignung verschiedener Messflaschchen und Szintillatorflussigkeiten zur Bestimmung von Tritium in Wasser),
W86-01142 7B

Laboratory Investigation and Analysis of a Ground-Water Flowmeter,
W86-01310 2F

MECHANIZATION
Mechanisation vs. Manual Execution of River Valley Projects in Maharashtra,
W86-01215 6A

MEDIAN SURVIVAL TIMES
Toxicity Curve Estimation: Fitting a Compartment Model to Median Survival Times,
W86-01152 5C

MEDITERRANEAN SEA
Fluxes and Residence Times of Hydrocarbons in the Coastal Mediterranean: How Important are the Biota,
W86-01115 5B

MERCURY
Mercury in Sediment in Swedish Forest Lakes,
W86-00952 5B

MESODINIUM
Role of Phytoplankton in the Dissolved Oxygen Budget of a Stratified Estuary,
W86-01197 2L

METABOLISM
Test Instructions for Measuring the Microbial Metabolic Activity in Water Samples,
W86-01302 5A

METALS
Drift Response of Aquatic Insects to Copper,
W86-00961 5C

W86-01318 5A

NORTHERN TERRITORY
Limnology of a Naturally Acidic Tropical Water System in Australia; I. General Description and Wet Season Characteristics,
W86-00923 2H

Limnology of a Naturally Acidic Tropical Water System in Australia; II. Dry Season Characteristics,
W86-00924 2H

Accumulation of Radium-226 by Populations of the Freshwater Mussel, Velesunio angasi, from the Alligator Rivers Uranium Province, Northern Territory, Australia,
W86-00972 5C

NORWAY
Some Hydraulic Properties of Sandy-Silty Norwegian Tills,
W86-01111 2G

Factor Interaction Influencing the Distribution of the Freshwater 'Shrimp' Gammarus,
W86-01162 2H

NOVA SCOTIA
Qualitative Analysis of the Pelagic Foodwebs of Three Acid-Impacted Lakes in Nova Scotia, Canada,
W86-01129 2H

Metal Mobilization in Home Well Water Systems in Nova Scotia,
W86-01264 5B

NUTRIENTS
About a Source of Nutrients in the Tropical River Rajang (N Borneo) in Relation to Future Impoundment,
W86-00921 6G

Mathematical Simulation of the Conversion and Transport of Nutrients in Drainage Areas - A Review of the Literature (Mathematische Simulation von Nahrstoffumwandlung und -t
in Einzugsgebieten-Literaturubersicht),
W86-00999

Elimination of Nutrients in the Rozko
voir,
W86-01002

Arsenic, Barium, Germanium, Tin, Dim
fide and Nutrient Biogeochemistry in C
Harbor, Florida, A Phosphorus-Enriche
ary,
W86-01113

Hydrology and Changes in the Nutri
Phytoplankton Levels in Goat Isla
Northern New Zealand,
W86-01127

Dissolved Inorganic Phosphorus in St
the Indian Arid Zone,
W86-01292

OCEAN DUMPING
Invertebrate Bioassays with North Se
Samples. I. Structural Effects on Emb
Larvae of Serpulids, Oysters and Sea
W86-01318

OIL
Stream Modeling of Nonconvetiona
Quality Parameters: Phenol, Cyanide, A
Oil and Grease,
W86-01234

OIL INDUSTRY
Genotoxic Activity of Particulate M
Petroleum Refinery Effluents,
W86-01283

OIL POLLUTION
Treatment of Industrial Wastewaters
Oily Emulsions, Surfactans and Sulphat
W86-01014

Considerations on Water, Oil and Air
Media,
W86-01176

OIL SHALE RETORT WATER
Identification and Treatability of Orga
Shale Retort Water,
W86-01060

OKLAHOMA
Statistical-Meteorological Evaluation
Operational Seeding Projects,
W86-01136

ONCHOCERCIASIS
Struggle Against Onchocerciasis in
Region: Impact of Insecticide Treatm
Non-target Aquatic Fauna (La Lut
l'Onchocercose dans la Region d
Impact des Traitements Insecticides su
Aquatique Non-cible),
W86-00966

ONTARIO
Pattern Recognition Techniques to
Benthic Invertebrate Trophic and C
Responses to Industrial Input,
W86-00934

OPTIMIZATION
Stochastic Optimization of a Multires
droelectric System: A Decompos
proach,
W86-01069

Optimization of a Spatially Variable
An Illustration for Irrigated Crops,
W86-01070

Synthesis Modeling of Municipal W
Treatment Systems,
W86-01188

EGON
pwelling and River Runoff as Sources of Dis-lved Nitrous Oxide to the Alsea Estuary, regon,
86-01117 2L

ANIC CARBON
ntribution to the Determination of Particulate rganic Carbon in Water Samples (Ein Beitrag r Bestimmung von Partikularem Organischen hlenstoff in Wasserproben),
86-01000 5A

bilization of Organic Carbon and Nitrogen in nsolidating Benthal Deposits,
86-01232 5D

ANIC COMPOUNDS
ntification and Treatability of Organics in Oil le Retort Water,
86-01060 5D

anic Removal Mechanisms in Biophysical atment Systems,
6-01240 5D

ANIC MATTER
uence of Organic Pollution on the Macroin-tebrate Communities of Mountain Streams,
6-00948 5C

cium Sulfate Solubility in Organic-Laden stewater,
6-01042 5D

cts of Dissolved Organic Matter on the eous Partitioning of Polynuclear Aromatic rocarbons,
6-01119 5B

Abundance Related to Organic Matter in Plata River Basin, South America,
-01149 2H

he Enhanced Biological Activated Carbon ation and its Effect on Organic Matter Re-al, and in Particular on AOC Reduction,
-01241 5F

NOPHOSPHATE PESTICIDES
inuous, Automatic Detection of Organo-phates and Carbamates in Water Utilizing me Microcalorimetry,
-01226 5A

NOPHOSPHORUS PESTICIDES
rmination of Trace Amounts of Organo-phorus Pesticides and Related Compounds oils and Sediments using Capillary Gas matography and a Nitrogen-Phosphorus ctor,
01083 5A

LATORY FLOW
and Where to Put a Discharge in an atory Flow,
01056 5B

AND FLOW
rity Solution of Overland Flow on Pervi-rface,
01092 2E

TION-REDUCTION POTENTIAL
urification with Controlled Redox Condi-
00945 5B

N BALANCE
n Balances in the Teltow-Canal - With l Regard to Heat Discharge from Lichter-Power Plant (Berlin, West) (Sauerstoffbi- im Teltowkanal - insbesondere unter dem s der Abwarmeeinleitung aus dem verk Lichterfelde (Berlin, West)),
1141 5B

OXYGEN DEMAND
Nutrient Regeneration and Oxygen Consumption by Sediments Along an Estuarine Salinity Gradient,
W86-01126 2L

OXYGEN DEPLETION
Modelling of Oxygen Depletion in Coastal Waters,
W86-01235 5C

OZONATION
Ozone Enhanced Biological Activated Carbon Filtration and its Effect on Organic Matter Removal, and in Particular on AOC Reduction,
W86-01241 5F

Ozonation of Non-Ionic Surfactants in Aqueous Solutions,
W86-01242 5F

Ozone Inactivation of Botulinum Type E Toxin,
W86-01267 5F

Factors Influencing the Ozone Inactivation of Enteric Viruses in Effluent,
W86-01268 5D

Purification of Polluted Source Water with Ozonation and Biological Activated Carbon,
W86-01269 5F

Preliminary Study of the Efficiency and Mechanism of THM Removal in the Ozonation and BAC Process,
W86-01270 5F

OZONE
Influence of Bubble Sizes on Ozone Solubility Utilization and Disinfection,
W86-01243 5D

High Temperature Treatment of Trinitrotoluene (TNT) and Cyclotrimethylene-Trinitramine (RDX) with Ozone and Ultrasound,
W86-01271 5D

PACIFIC OCEAN
Estimation of Discharge and Loads from the Rivers Flowing into Littoral Seas of China (in Chinese),
W86-01167 2J

PACKED BED REACTORS
Application of Anaerobic Packed-Bed Reactors to Industrial Waste-Water Treatment,
W86-01019 5D

PALEOLIMNOLOGY
Assessment of Ecological Changes During the Recent History of Lake Ontario Based on Siliceous Algal Microfossils Preserved in the Sediments,
W86-01110 2H

PARAGUAY
Fish Abundance Related to Organic Matter in the Plata River Basin, South America,
W86-01149 2H

PARAMETER STRUCTURE
Identification of Parameter Structure in Groundwater Inverse Problem,
W86-01078 2F

PARANA RIVER
Fish Abundance Related to Organic Matter in the Plata River Basin, South America,
W86-01149 2H

PARASITES
Cadmium Partitioning and Related Effects in Parasitized and Non-Parasitized Mosquitofish (Gambusia affinis: Poeciliidae),
W86-00960 5C

Epidemiological Evidence for Helminth and Cholera Transmission by Vegetables Irrigated with Wastewater: Jerusalem - A Case Study,
W86-01173 5D

PARATHION
Effects of Acute Parathion Pollution on Macroinvertebrates in a Stream,
W86-00963 5C

PARTICLE STABILITY
Colloidal Stability of Particles in Lakes: Measurement and Significance,
W86-01194 2H

PARTICULATE MATTER
Contribution to the Determination of Particulate Organic Carbon in Water Samples (Ein Beitrag zur Bestimmung von Partikularem Organischen Kohlenstoff in Wasserproben),
W86-01000 5A

Variations in the Natural Abundance of 15N in Estuarine Suspended Particulate Matter: A Specific Indicator of Biological Processing,
W86-01121 2L

Colloidal Stability of Particles in Lakes: Measurement and Significance,
W86-01194 2H

Genotoxic Activity of Particulate Material in Petroleum Refinery Effluents,
W86-01283 5C

PATH OF POLLUTANTS
Errors from Using Conservation of Buoyancy Concept in Plume Computations,
W86-01051 5B

Turbulent Dispersion from a Steady Two-Dimensional Horizontal Source,
W86-01055 5B

When and Where to Put a Discharge in an Oscillatory Flow,
W86-01056 5B

Ecotoxicological Aspects of Pulp and Paper Mill Effluents Discharged to an Inland Water System: Distribution in Water, and Toxicant Residues and Physiological Effects in Caged Fish (Salmo gairdneri),
W86-01161 5C

New Method of Contaminant Plume Analysis,
W86-01309 5B

Movement of Volatile Organics Through a Fractured Rock Aquifer,
W86-01311 5B

PEARSON III
Relative Accuracy of Log Pearson III Procedures,
W86-01091 2E

PEATBOGS
Use of the Rb/K Ratio to Evaluate Potassium Nutrition of Peatlands,
W86-01164 2L

PEATLANDS
Use of the Rb/K Ratio to Evaluate Potassium Nutrition of Peatlands,
W86-01164 2L

PENTACHLOROPHENOL
Fate and Effects of Pentachlorophenol in Hard- and Soft-Water Microcosms,
W86-00998 5B

Growth and Feeding Behaviour Responses of Largemouth Bass (Micropterus salmoides) Exposed to PCP,
W86-01157 5C

PERACETIC ACID
Use of Peracetic Acid in Operational Sewage Sludge Disposal to Pasture,
W86-01175 5D

PERCOLATION
Estimating Vertical Soil Moisture Flux at a Land Treatment Site,
W86-01312 2G

PERIPHYTON
Dynamics of Colonization in an Experimental Channel, Fed by the Po River Waters,
W86-00920 2H

Comparison of Planktonic and Periphytic Microalgal Parameters as Indicators of Eutrophication in a Baltic Archipelago: Annual Succession of Community Parameters,
W86-00931 7B

PERMEABILITY COEFFICIENT
Decrease of Hydraulic Conductivity in Sand at the Interface Between Seawater and Dilute Clay Suspensions,
W86-01300 2F

PESTICIDE TOXICITY
Use of Limnocorrals for Pesticide Toxicity Studies: Effect on Zooplankton Composition and Dynamics,
W86-00964 5A

PESTICIDES
Effects of 2,4-D on Natural Phytoplankton Systems in Association with Myriophyllum spicatum,
W86-00965 5C

Influence of Pesticides in the Pollution of Continental African Waters (Incidence des Pesticides dans la Pollution des Eaux Continentales Africaines),
W86-00967 5C

Assessment of the Significant Physicochemical Interactions Involved in Pesticide Diffusion within a Pesticide-Sediment-Water System,
W86-00995 5B

Removal of Pesticides in Water by Microbial Cells Adsorbed to Magnetite,
W86-01057 5F

PHENOLICS
Ecotoxicological Aspects of Pulp and Paper Mill Effluents Discharged to an Inland Water System: Distribution in Water, and Toxicant Residues and Physiological Effects in Caged Fish (Salmo gairdneri),
W86-01161 5C

PHENOLS
Effects of Activated Carbon on the Reactions of Combined Chlorine with Phenols,
W86-01066 5F

Stream Modeling of Nonconvetional Water Quality Parameters: Phenol, Cyanide, Ammonia, Oil and Grease,
W86-01234 5B

Organic Removal Mechanisms in Biophysical Treatment Systems,
W86-01240 5D

Brominated Phenols and Anisoles in River and Marine Sediments in Japan,
W86-01287 5B

PHOSPHATES
Effects of Waterlogging and Subsequent Drainage of a Pasture Soil on Phosphate Sorption, Extractable Phosphate and Oxalate-Extractable Iron,
W86-01038 2K

Calculation of Transport Coefficients of Phosphate and Calcium Fluxes across the Sediment-Water Interface, from Experiments with Undisturbed Sediment Cores,
W86-01233 2J

PHOSPHORUS
Movement of Septic Tank Effluent through Sandy Soils near Perth. II. Movement of Phosphorus,
W86-01035 5B

Phosphorus, Nitrogen and Chlorophyll-a Concentrations in a Typical Dutch Polder Lake, Tjeukemeer, in Relation to its Water Regime Between 1968 and 1982,
W86-01196 2H

Restoration of Lake Veluwe, The Netherlands, by Reduction of Phosphorus Loading and Flushing,
W86-01198 5G

Dissolved Inorganic Phosphorus in Streams of the Indian Arid Zone,
W86-01292 2J

PHOTOOXIDATION
Sunlight Photooxidation of Organic Pollutants in Wastewater,
W86-01187 5D

PHOTOSYNTHESIS
Photosynthetic Activity of Dominant Algal Species in Eutrophic Shallow Lake (Grosser Muggelsee, Berlin) Investigated by Microautoradiography,
W86-01131 2H

PHYSICOCHEMICAL CHARACTERISTICS
Limnological Investigation of the Rivers Uracoa, Yabo, Morichal Largo and Claro in the Eastern Plains of Venezuela,
W86-00928 2H

River Typology of Sao Paulo State, Brazil,
W86-00929 2H

Some Physical and Chemical Properties of Water from an Undisturbed Tropical Catchment Area (Guma Dam, Sierra Leone),
W86-01134 2H

Factor Interaction Influencing the Distribution of the Freshwater 'Shrimp' Gammarus,
W86-01162 2H

PHYSICOCHEMICAL PROPERTIES
Compositional and Structural Analysis of Phytoplankton in Lake Khurpatal, (U.P.), India,
W86-01133 2H

PHYTOPLANKTON
Limnological Investigation of the Rivers Uracoa, Yabo, Morichal Largo and Claro in the Eastern Plains of Venezuela,
W86-00928 2H

Comparison of Planktonic and Periphytic Microalgal Parameters as Indicators of Eutrophication in a Baltic Archipelago: Annual Succession of Community Parameters,
W86-00931 7B

Phytoplankton Dynamics in a Hypertrophic Brackish-Water Bay,
W86-00932 5C

Mine Waste Discharge Rich in Copper - An Example of Effects on Planktonic Communities,
W86-00959 5C

Effects of 2,4-D on Natural Phytoplankton Systems in Association with Myriophyllum spicatum,
W86-00965 5C

Some Aspects on Algal Toxicity To Natural Phytoplankton,
W86-00969

Effects of Power Plant Entrainment o plankton Response,
W86-00973

Effects of Wind, Phytoplankton and Discontinuities upon Ammonia Distrib Liverpool Bay,
W86-01120

Hydrology and Changes in the Nutr Phytoplankton Levels in Goat Isla Northern New Zealand,
W86-01127

Experimental Studies on the Suscep Freshwater Phytoplankton to Variation ity in the Fjord of Saguenay (St. L Estuary), Canada (Etudes experimenta sensibilite du phytoplancton d'eau d variations de salinite dans le fjord du (Estuaire du St-Laurent), Canada),
W86-01128

Effects of Entrainment on Phytoplan mary Production at Four Thermal Elec erating Stations on the Laurentian Gre
W86-01132

Compositional and Structural Analysis plankton in Lake Khurpatal, (U.P.), Ind
W86-01133

PHYTOTOXICITY
Some Aspects on Algal Toxicity T Natural Phytoplankton,
W86-00969

PIEDMONT REGION
Inventorying Ground Water in C Rocks of Piedmont Region,
W86-01104

PIERS
Effect of Pier Spacing on Scour Arou Piers,
W86-01095

PIPELINES
Model for Beam-Mode Buckling of Bu lines,
W86-01079

PIPING
Model for Piping-Plugging in Earth tures,
W86-01087

PLANNING
Multi-Objective Decision-Making in W posal Planning,
W86-01044

Problems in Water Resources Utilizati
W86-01206

Hydropower Scenario,
W86-01222

Developing Regional Water Systen Netherlands,
W86-01263

PLANT PHYSIOLOGY
Coping with Drought by the Sea,
W86-01112

Stomatal Responses and Water Relati calyptus pauciflora in Summer Along tional Gradient,
W86-01163

PLATA RIVER BASIN
Fish Abundance Related to Organic the Plata River Basin, South America,
W86-01149

LEUSTOPHYTES
Changes in the Pleustic Macrophyte Flora of 54 Small Finnish Lakes in 30 Years,
W86-01156 2H

LUGGING
Model for Piping-Plugging in Earthen Structures,
W86-01087 8D

LUMAS COUNTY
Multilevel Approach to the Assessment of Ecotoxicological Effects in a Heavy Metal Polluted Stream,
W86-00953 5C

UMBING
Metal Mobilization in Home Well Water Systems in Nova Scotia,
W86-01264 5B

UMES
Errors from Using Conservation of Buoyancy Concept in Plume Computations,
W86-01051 5B

New Method of Contaminant Plume Analysis,
W86-01309 5B

RIVER
Dynamics of Colonization in an Experimental Channel, Fed by the Po River Waters,
W86-00920 2H

Cadmium and Chromium in the Waters, Sediments and Biota of the Val Parma Running Water Ecosystem,
W86-00957 5B

LAND
Diatom Communities of the Polluted Rivers of Central Poland (Les Communautes des Diatomees dans les Rivieres Polluees de la Pologne Centrale),
W86-00947 5C

Influence of Organic Pollution on the Macroinvertebrate Communities of Mountain Streams,
W86-00948 5C

Chemical Composition of Bottom Sediments and Phytoplankton in the Man-made Lake Zemborzyce near Lublin,
W86-01319 2H

ICY MAKING
Organic Pollution; Management of Fresh Waters: Input of Scientific Data Into Policy Formulation in the United States,
W86-00933 6A

LUTANT IDENTIFICATION
Determination of Trace Amounts of Organophosphorus Pesticides and Related Compounds in Soils and Sediments using Capillary Gas Chromatography and a Nitrogen-Phosphorus Detector,
W86-01083 5A

LUTION LOAD
Estimation of the Loads of Some List I and II Substances to United Kingdom Tidal Waters - a Comparison with Previous Estimates,
W86-01025 5G

Contribution of Agricultural Loading to Eutrophication in Finnish Lakes,
W86-01247 5B

Collection and Analysis of Urban Runoff Data in Finland,
W86-01251 5D

POLYNUCLEAR AROMATIC HYDROCARBONS
Effects of Dissolved Organic Matter on the Aqueous Partitioning of Polynuclear Aromatic Hydrocarbons,
W86-01119 5B

POLYNUCLEAR HYDROCARBONS
Effect of Polynuclear Hydrocarbons on Algal Nitrogen Fixation (Acetylene Reduction),
W86-01285 5C

POORVOO
Phytoplankton Dynamics in a Hypertrophic Brackish-Water Bay,
W86-00932 5C

POROUS MEDIA
Practical Method for Modeling Fluid and Heat Flow in Fractured Porous Media,
W86-01138 2F

Considerations on Water, Oil and Air in Porous Media,
W86-01176 5B

PORTUGAL
Mine Waste Discharge Rich in Copper - An Example of Effects on Planktonic Communities,
W86-00959 5C

POTASSIUM
Use of the Rb/K Ratio to Evaluate Potassium Nutrition of Peatlands,
W86-01164 2L

POWERPLANTS
Effects of Power Plant Entrainment on Phytoplankton Response,
W86-00973 5C

PREDICTION
Predicted Extreme High Tides for California: 1983-2000,
W86-01100 2L

PREDICTIONS
Two-Dimensional Calculation of Tide by Explicit Weighted Residual Method - I Shibushi Bay,
W86-01144 2L

PRESSURE TUNNELS
Power Conduits for High-Head Plants,
W86-01277 8A

PRIMARY PRODUCTION
Stratification and Primary Production in a Small Brackish Lake Studied by Close-Interval Siphon Sampling,
W86-00930 2H

Enhancement of Marine Primary Production by Nitrogen-Enriched Acid Rain,
W86-01172 5C

PRIMARY PRODUCTIVITY
Suspended Sediment - Microbial Interactions in a Shallow Turbid Impoundment,
W86-00979 2H

PROBABILITY DISTRIBUTION
Relative Accuracy of Log Pearson III Procedures,
W86-01091 2E

PRODUCTIVITY
Composition and Productivity of the Benthic Macroinvertebrate Community of a Subtropical Reservoir,
W86-01130 2H

PROTOZOANS
Microfauna Distribution in Shallow Macrophyte-Covered Basins,
W86-00951 5D

PUGET SOUND
Cytotoxicity/Genotoxicity: The Application of Cell Culture Techniques to the Measurement of Marine Sediment Pollution,
W86-01158 5C

PULP AND PAPER INDUSTRY
Pattern Recognition Techniques to Determine Benthic Invertebrate Trophic and Community Responses to Industrial Input,
W86-00934 5C

Ecotoxicological Aspects of Pulp and Paper Mill Effluents Discharged to an Inland Water System: Distribution in Water, and Toxicant Residues and Physiological Effects in Caged Fish (Salmo gairdneri),
W86-01161 5C

PULP WASTES
Persistent Chemicals in Pulp Mill Effluents Occurrence and Behaviour in an Activated Sludge Treatment Plant,
W86-01064 5D

PUMP-TURBINE
Tests on a French Adjustable Two-Stage Pump-Turbine,
W86-01274 8C

PUMPED STORAGE
Energy Storage: Developments in Pumped-Storage,
W86-01272 8C

Power Conduits for High-Head Plants,
W86-01277 8A

PUMPING WELLS
Quality of Water in an Aquifer and its Manifestation In Pumping Wells,
W86-01299 2F

PUMPS
Pumps Crucial to Success of Long-distance Aqueducts,
W86-01085 8C

PUNJAB
Low Head Canal Power Development in Punjab,
W86-01221 6B

PUTREFACTION
Source of Hydrogen Sulfide in Anoxic Sediment,
W86-01063 2H

QUEBEC
Experimental Studies on the Susceptibility of Freshwater Phytoplankton to Variation of Salinity in the Fjord of Saguenay (St. Lawrence Estuary), Canada (Etudes experimentalles sur la sensibilite du phytoplancton d'eau douce aux variations de salinite dans le fjord du Saguenay (Estuaire du St-Laurent), Canada),
W86-01128 2L

Simulating Fish Redistribution in the LG-2 Reservoir After Flooding,
W86-01166 8I

QUEENSLAND
Estimated Store of Soluble Salts in the Lake Eyre Catchment in Queensland and their Possible Transport in Streamflow to the Lake,
W86-01031 2A

RABAGAO RIVER
Mine Waste Discharge Rich in Copper - An Example of Effects on Planktonic Communities,
W86-00959 5C

RADIOACTIVE WASTES
Water Plants, an Indicator for Radioactive Contamination (Wasserpflanzen, ein Indikator for Radioaktive Veruneinigungen),
W86-00971 5A

RADIOISOTOPES
Radionuclide Content Measurement and Interpretation in Fish from the Upper Rhone River in France (Mesure et Interpretation des Teneurs en Radionucleides de Poissons du Haut-Rhone Francais),
W86-00970 5A

RADIUM RADIOISOTOPES
Accumulation of Radium-226 by Populations of the Freshwater Mussel, Velesunio angasi, from the Alligator Rivers Uranium Province, Northern Territory, Australia,
W86-00972 5C

RAIN
Effect of Kinetic Energy of Excess Rainfall on Soil Loss from Non-vegetated Plots,
W86-01028 2J

RAINFALL
Statistical-Meteorological Evaluation of Two Operational Seeding Projects,
W86-01136 3B

Highest Observed 1 to 10-Day Point and Areal Rainfall over Kerala State,
W86-01223 2B

Response of Groundwater Levels to Rainfall and to Leaf Growth of Farm Plantations Near Salt Seeps,
W86-01290 2F

Recent Changes in Summer Rainfall Values Measured at Long Ashton,
W86-01303 2B

RAINFALL-RUNOFF RELATIONSHIPS
Stochastic Models Applied to Evaluating Hydrologic Changes,
W86-01293 2A

RAINFALL SIMULATORS
Field Rainfall Simulator Studies on Two Clay Soils of the Darling Downs, Queensland. III; An Evaluation of Current Methods for Deriving Soil Erodibilities (K Factors),
W86-01037 2J

RAUTALAMPI
Grayling (Thymallus thymallus (L.)) in the Lower Part of the Rautalampi Watercourse, Finnish Lake District,
W86-00974 2H

RECONSTRUCTION
Reconstruction of a Dam Water Intake Under Conditions of Continuous Operation of the Reservoir,
W86-00990 8A

REGIONALIZATION
Regionalization: A Decade Points to More Change,
W86-01086 6E

REINFORCED EARTH
Technology of Reinforced Earth Walls,
W86-01214 8D

REMOTE SENSING
Evapotranspiration Derived from Satellite Observed Surface Temperatures,
W86-01135 2D

Machine Classification of Freshwater Ice Types from Landsat-1 Digital Data Using Ice Albedos as Training Sets,
W86-01288 2C

RESERVOIR FISHERIES
Simulating Fish Redistribution in the LG-2 Reservoir After Flooding,
W86-01166 8I

RESERVOIR SITING
Investigation of Dam Sites: Modern Practices,
W86-01210 8E

RESERVOIRS
About a Source of Nutrients in the Tropical River Rajang (N Borneo) in Relation to Future Impoundment,
W86-00921 6G

Water Quality Control in Impoundments,
W86-01006 5G

Reservoir Impacts: A Synthesis of a 10-Year Research Project,
W86-01071 6G

Composition and Productivity of the Benthic Macroinvertebrate Community of a Subtropical Reservoir,
W86-01130 2H

Analytical Representation of the van Everdingen-Hurst Aquifer Influence Functions for Reservoir Simulation,
W86-01139 2F

Detergents for Reservoirs and Colony Increases in Potable Water (Reinigungsmittel fur Behalter und Koloniezahl-erhohungen im Trinkwasser),
W86-01140 5F

Simulating Fish Redistribution in the LG-2 Reservoir After Flooding,
W86-01166 8I

Asphaltic Concrete Linings for Pumped-Storage Reservoirs,
W86-01273 8F

Analysis of the Benthic Macroinvertebrate Community of a Fluctuating River-Reservoir Zone in Middle Tennessee,
W86-01317 6G

RESIN ACIDS
Ecotoxicological Aspects of Pulp and Paper Mill Effluents Discharged to an Inland Water System: Distribution in Water, and Toxicant Residues and Physiological Effects in Caged Fish (Salmo gairdneri),
W86-01161 5C

RESOURCE DEVELOPMENT
Energy Extraction From Lake Sediments with Heat Exchangers. Effects on Water Quality, Sediment, Bottom Fauna, and Fish,
W86-00938 6G

RESOURCE MANAGEMENT
Organic Pollution; Management of Fresh Waters: Input of Scientific Data Into Policy Formulation in the United States,
W86-00933 6A

RESPIRATION
Short-time Determination of the Quality of the Effluent from Activated Sludge Plants on the Basis of the Respiration Activity (Kurzzeitermittlung der Ablaufqualitat von Belebtschlammanlagen anhand der Atmungsaktivitat),
W86-01013 5D

RESUSPENSION
Quantification of Wind Induced Resuspension in a Shallow Lake,
W86-01230 2H

Sedimentation, Mineralization and Resuspension of Sludge in a Sewerage System: A Case Study,
W86-01255 5D

REVIEWS
Mathematical Simulation of the Conversion and Transport of Nutrients in Drainage Areas - A Review of the Literature (Mathematische Simulation von Nahrstoffumwandlung und -tr in Einzugsgebieten-Literaturubersicht),
W86-00999

RHINE RIVER
Amsterdam Water Supply,
W86-01260

RHONE RIVER
Radionuclide Content Measurement an pretation in Fish from the Upper Rhone France (Mesure et Interpretation des Te Radionucleides de Poissons du Hau Francais),
W86-00970

Contribution of Backwaters to the Ec Fish Populations in Large Rivers. Pre Results on Fish Migrations within a S and from the Side Arm to the Main Ch the Rhone,
W86-00975

RISK ANALYSIS
Risk Analysis for Seismic Design of Dams,
W86-01090

RIVER
Estimation of Discharge and Loads Rivers Flowing into Littoral Seas of Chinese),
W86-01167

RIVER BEDS
Direct Measurements of Secondary Cu a Meandering Sand-Bed River,
W86-01171

RIVER DIFFUSERS
Comparison of Two River Diffuser Mo
W86-01093

RIVER DON
Development and Use of an Empiric for Dissolved Oxygen in the River D deenshire,
W86-00937

RIVER ERMS
Use of Bacteria Attached to Submerge phytes and Glass Slides as Indicators creasing Water Pollution,
W86-00943

RIVER FLOW
Estimation of Discharge and Loads Rivers Flowing into Littoral Seas of Chinese),

SELECTED WATER RESOURCES ABSTRACTS

VOLUME 19, NUMBER 5
MAY 1986

-- W86-01919
SWRABW

SELECTED WATER RESOURCES ABSTRACTS (SWRA) is produced by the Geological Survey, U.S. Department of the Interior, and published monthly by the National Technical Information Service (NTIS), U.S. Department of Commerce.

SWRA is available to Federal agencies and their contractors or grantees in water resources research upon request, citing contract or grant number and sponsoring agency. Write: Water Resources Division, U.S. Geological Survey, MS 425, Reston, VA 22092. The **SWRA Journal** is also available on subscription from NTIS, 5285 Port Royal Road, Springfield, VA 22161. Annual subscription rates for the North American Continent are: Journal only, $115, Journal and Annual Indexes, $145; Indexes only, $50. Other addressees, write for prices.

Some documents abstracted in this journal can be purchased from NTIS. Price codes are given in the entries and a current code-price conversion table is printed on the outside back cover. Other documents are available from originating organizations or authors as indicated in the citation.

SELECTED WATER RESOURCES ABSTRACTS

A monthly publication of the Geological Survey
U.S. Department of the Interior

VOLUME 19, NUMBER 5
MAY 1986

W86-01320 -- W86-01919

The Secretary of the Interior has determined that the publication of the periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Office of Management and Budget through September 30, 1986.

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

PREFACE

Selected Water Resources Abstracts, a monthly journal, includes abstracts of current and earlier pertinent monographs, journal articles, reports, and other publication formats. These documents cover water resources as treated in the life, physical, and social sciences and the related engineering and legal aspects of the characteristics, supply condition, conservation, control, use, or management of water resources. Each abstract includes a full bibliographic citation and a set of descriptors which are listed in the **Water Resources Thesaurus.** The abstract entries are classified into 10 fields and 60 groups similar to the water resources research categories established by the Committee on Water Resources Research of the then Federal Council for Science and Technology.

Selected Water Resources Abstracts is designed to serve the scientific and technical information needs of scientists, engineers, and managers as one of several services of the Water Resources Scientific Information Center. The cumulative SWRA file from 1968 and monthly updates are available also in magnetic tape through lease from NTIS.

THE WATER RESOURCES SCIENTIFIC INFORMATION CENTER DOES NOT PROVIDE COPIES OF DOCUMENTS ABSTRACTED IN THIS JOURNAL. Sufficient bibliographic information is given to enable readers to order the desired documents from local libraries or other sources.

Comments and suggestions concerning the contents and arrangement of this bulletin are welcome.

CONTENTS

SUBJECT FIELDS AND GROUPS

Please use the edge index on the back cover to locate Subject Fields and Indexes.

01 NATURE OF WATER

Includes the following Groups: Properties; Aqueous Solutions and Suspensions.

02 WATER CYCLE

Includes the following Groups: General; Precipitation; Snow, Ice, and Frost; Evaporation and Transpiratio Streamflow and Runoff; Groundwater; Water in Soils; Lakes; Water in Plants; Erosion and Sedimentatio Chemical Processes; Estuaries.

03 WATER SUPPLY AUGMENTATION AND CONSERVATION

Includes the following Groups: Saline Water Conversion; Water Yield Improvement; Use of Water of Impair Quality; Conservation in Domestic and Municipal Use; Conservation in Industry; Conservation in Agricultur

04 WATER QUANTITY MANAGEMENT AND CONTROL

Includes the following Groups: Control of Water on the Surface; Groundwater Management; Effects on Water Man's Nonwater Activities; Watershed Protection.

05 WATER QUALITY MANAGEMENT AND PROTECTION

Includes the following Groups: Identification of Pollutants; Sources of Pollution; Effects of Pollution; Was Treatment Processes; Ultimate Disposal of Wastes; Water Treatment and Quality Alteration; Water Qual Control.

06 WATER RESOURCES PLANNING

Includes the following Groups: Techniques of Planning; Evaluation Process; Cost Allocation, Cost Sharin Pricing/Repayment; Water Demand; Water Law and Institutions; Nonstructural Alternatives; Ecologic Impact Water Development.

07 RESOURCES DATA

Includes the following Groups: Network Design; Data Acquisition; Evaluation, Processing and Publication

08 ENGINEERING WORKS

Includes the following Groups: Structures; Hydraulics; Hydraulic Machinery; Soil Mechanics; Rock Mechan and Geology; Concrete; Materials; Rapid Excavation; Fisheries Engineering.

09 MANPOWER, GRANTS, AND FACILITIES

Includes the following Groups: Education—Extramural; Education—In-House; Research Facilities; Gran Contracts, and Research Act Allotments.

10 SCIENTIFIC AND TECHNICAL INFORMATION

Includes the following Groups: Acquisition and Processing; Reference and Retrieval; Secondary Publicati and Distribution; Specialized Information Center Services; Translations; Preparation of Reviews.

RECURRENCE INTERVAL OF DROUGHT EVENTS THROUGH STOCHASTIC ANALYSIS OF RAINFALL AND STREAMFLOW DATA,
Melbourne Univ., Parkville (Australia). Dept. of Civil Engineering.
R. Srikanthan, and T. A. McMahon.
Hydrological Sciences Journal, Vol. 30, No. 2, p 197-206, June, 1985. 1 Fig, 4 Tab, 11 Ref.

Descriptors: *Drought, *Recurrence intervals, *Rainfall, *Streamflow, *Stochastic hydrology, *Victoria, *Australia, Temporal distribution, Model studies, Data interpretation.

The efficient management of an agricultural system or the operation of a water supply scheme requires knowledge about critical droughts, such as their length, severity and frequency of occurrence. Several theoretical distributions are fitted to drought events of up to one year's duration and the average recurrence intervals calculated. A methodology based on stochastically generated data is proposed and used to obtain the average recurrence intervals of events of duration longer than one year. These methods are applied to five river basins in Victoria, Australia. The accuracy of the method is dependent on the adequacy of the generating model. (Author's abstract)

GENERATION OF DELAYED PEAKS IN STREAM DISCHARGE,
Oxford Univ. (England). Geography School.
T. P. Burt, and D. P. Butcher.
Journal of Hydrology, Vol. 78, No. 3/4, p 361-378, June, 1985. 13 Fig, 1 Tab, 25 Ref.

Descriptors: *Storm seepage, *Stream discharge, *Delayed peaks, Flood peaks, Computer models, Simulation, Slopes, Soil water, Rainfall, Runoff, England.

Where deep permeable soils overlie impermeable bedrock and where steep hillslopes border a narrow floodplain, subsurface stormflow dominates the hydrograph. In such cases delayed peaks in stream discharge may occur several days after rainfall, providing the major volumetric response and possibly also the highest peak discharge. The general occurrence of such delayed peaks is considered, making reference to field data from two small drainage basins in southwest England, and to the results of computer simulations using a distributed hillslope model. The importance of soil-water convergence into hillslope hollows is stressed. The relative roles of rainfall and antecedent soil moisture in controlling the size and timing of the delayed peak is discussed. The implications of the results for hillslope runoff modelling are briefly considered. (Author's abstract)
W86-01480

MACROSCOPIC ESTIMATION OF AVAILABLE WATER RESOURCES IN KAGOSHIMA PREFECTURE, JAPAN (IN JAPANESE),
Kagoshima Prefectural Office (Japan). Planning Dept.
Y. Osako, T. Tsuyuki, S. Koriyama, and K. Hyakumoto.
Reports of the Faculty of Science, Kagoshima University, No. 17, p 89-101, December, 1985. 5 Fig, 7 Tab, 8 Ref.

Descriptors: *Water resources, *Kagoshima, *Japan, *Hydrologic cycle, Groundwater, Surface water, Precipitation, Runoff.

Proper planning for the development and management of water resources requires the quantitative estimation of available water including surface and ground water. A method of macro-estimate of available water resources is presented using rainfall, streamflow and evaporation data accumulated by Kagoshima Weather Bureau and Kagoshima Prefectural Office. In general, precipitation minus evaporation equals streamflow plus percolation. As percolating ground water ultimately reaches streams, quantities of water resources or surface runoff are calculated by annual precipitation minus evapo-transpiration. Compared with measured stream flow data, those calculated figures are rather large. This is presumably due to the nonuniform distribution of precipitation by orographic effect. The average annual runoff coefficient of rivers in Kagoshima Prefecture is 0.65. To estimate the safe yield, the annual low precipitation and runoff data in 1942 are selected to be expected to occur once every ten years. Rivers in Kagoshima Prefecture can be classified into four types by unit flow states (illustrated in tables). Each type of rivers reflects the geologic conditions of their drainage basins. Rivers of type I are characterized by very stable flow states through the year. Pyroclastic flow deposits or so-called shirasu are widely distributed in the basin of rivers of type I. Under a natural flow state, ratios of quantities of available surface water to total runoff in each type of river are 48.0%, 34.0%, 24.0%, and 18.0% respectively. Calculated quantities of available water under a natural flow state in Kagoshima Prefecture are given. (Author's abstract)

MAXIMUM LIKELIHOOD PARAMETER ESTIMATION OF HYDROLOGIC SPATIAL PROCESSES BY THE GAUSS-NEWTON METHOD,
Iowa Inst. of Hydraulic Research, Iowa City.
P. K. Kitanidis, and R. W. Lane.
Journal of Hydrology, Vol. 79, No. 1/2, p 53-71, July, 1985. 2 Fig, 2 Tab, 26 Ref. Department of the Interior project CT 381702, NSF grant CME-8106577.

Descriptors: *Maximum likelihood, *Parameter estimation, *Hydrology, Mathematical studies, Spatial properties, Gauss-Newton method, Optimization.

The Gauss-Newton method for maximum likelihood (ML) parameter estimation of spatially correlated hydrologic fields is described with emphasis on computational aspects associated with its implementation. The essence of the Gauss-Newton method is that, for purposes of applying Newton's optimization method, the Hessian of the function to be minimized is replaced by its average value eliminating the need to calculate second derivatives. In ML estimation, the parameters are determined through minimization of the negative log-likelihood function and the average of the Hessian is known as the information matrix. The information matrix provides a lower bound to the covariance matrix of parameter estimation error. Methodologies to account for near-singular information matrix and to enforce lower or upper bounds in the parameters are described. A general method to eliminate the bias in covariance parameter estimates caused by unknown drift parameters is also presented. Some simple examples are presented to illustrate the potential advantages of Gauss-Newton. The conditions under which this method should perform well are also discussed. (Author's abstract)
W86-01656

CORRELATION BETWEEN SAMPLE FIRST AUTOCORRELATION COEFFICIENT AND EXTREME HYDROLOGIC RUNS,
George Washington Univ., Washington, DC. International Water Resources Inst.
V. Yevjevich, and J. T. B. Obeysekera.
Journal of Hydrology, Vol. 79, No. 1/2, p 171-186, July, 1985. 9 Fig, 9 Tab, 15 Ref. NSF grant CEE-8405289.

Group 2A—General

Descriptors: *Runoff, *Autocorrelation, *Hydrologic series, Drought, Hydrologic models, Water demand, Autoregression.

Differences between the annual runoff series, as the systems water supply and the annual output series, as the systems water demand, define various types of runs. The extreme runs of samples of these differences are positively correlated with the parameters of series dependence in general, and series first autocorrelation coefficient r1, estimated from these samples, in particular. This correlation is made between the estimated r1 and each of the three variables of sample extreme runs. These variables are defined as summations of n longest or largest positive and longest or largest negative sample extreme runs. The resulting regression equations of r1 versus these variables permit an alternative estimation of rho 1, if this estimate is needed for any purpose. As expected, these correlations are always positive and relatively high. To show how high these correlations are, two models are used to generate samples of different sizes with various population p1 values and to study the resulting correlation: (1) first-order autoregressive normal process; and (2) dependent lognormal process, obtained by the exponential transformation of the first-order autoregressive normal process. (Author's abstract)

WATERSHED COMPUTER MODELS,
Flaherty-Giavara Associates, New Haven, CT.
J. G. MacBroom.
Journal of the New England Water Works Association, Vol. 99, No. 2, p 187-199, June, 1985. 4 Fig.

Descriptors: *Computers, *Model studies, *Watershed management, Simulation, Water supply development, Water resources, Water management, Reservoir operation.

Two types of computer models are described that are useful tools for analyzing water supply reservoirs and dams. The use of watershed computer models is of particular importance to water supply utilities that depend on surface water reservoirs for raw water, and who are responding to increased demand for dependable supplies. In addition, computer models are critical for evaluating low flow conditions downstream of reservoirs, hydropower potential at reservoirs, and dam safety. The first type discussed in a continuous simulation model that mathematically represents the flow and storage of water over an extended period of time and is commonly used to determine safe yields. The second model mathematically simulates a single rainfall event, and is typically used to evaluate flood flows and spillway capacity at dams. The watershed computer models represent a major improvement in the ability to plan, manage, and operate water supply reservoirs. The use of calibrated computer models is vital in gaining a better understanding of reservoir operations, limitations, and potential development of resources. (Baker-IVI)
W86-01754

DETERMINATION OF GROWING SEASON SOIL WATER DEFICITS ON A FORESTED SLOPE USING WATER BALANCE ANALYSIS,
British Columbia Univ., Vancouver. Dept. of Soil Science.
D. G. Giles, T. A. Black, and D. L. Spittlehouse.
Canadian Journal of Forest Research, Vol. 15, No. 1, p 107-114, February, 1985. 5 Fig, 4 Tab, 38 Ref.

Descriptors: *Soil water, *Soil moisture deficiency, *Forests, *Hydrologic budget, Slopes, Solar radiation, Air temperature, Rainfall, Root zone, Storage capacity, Elevation, Evapotranspiration.

Coefficients for the calculation of soil water balance components at seven sites on a forested slope were determined using only measurements of daily solar irradiance, maximum and minimum air temperature and rainfall, and weekly root zone soil water content during a 2-year period. Site parameters required were root zone depth, soil water retention characteristics, and rainfall interception coefficients. Based on daytime net radiation, the Priestley-Taylor evapotranspiration coefficient (alpha) was found to be 0.73 +/- 0.07, which is similar to values reported in other conifer forest studies. Growing season water deficit increased with decreasing root zone water storage capacity, which was mainly a function of root zone depth. A comparison between high and low elevations on the slope showed 100-year site indices ranging from 17 to 53 m corresponding to growing season soil water deficits during the driest year of the study, ranging from 79 to 4 mm. Basal area annual increments were found to be correlated with soil water deficits and growing season transpiration, both for the study period and when both variables were averaged over the last 18 years. (Author's abstract)

YEAR OF WORLD WIDE EXTREMES; FLOODS AND DROUGHTS,
National Environmental Satellite, Data, and Information Service, Washington, DC. Climate Assessment Branch.
D. LeComte.
Weatherwise, Vol. 37, No. 1, p 8-11, 15-17 and 19, February, 1984. 10 Fig.

Descriptors: *Weather patterns, *Drought, *Floods, Rainfall, Storms, Climate, Heat, Cold, Monsoons, Hurricanes, Cyclones.

The year 1983 was a year of extremes - severe drought, heavy rains, extreme heat, unseasonable cold, the culmination of the El Nino event. Specific events cited in this review include the record floods in the California, Utah and Colorado areas, torrential rains in Ecuador, ferocious storms in winter and spring which swept eastward across the North Atlantic into northern Europe and Scandinavia, drought in southern Africa, fires brought on by extreme heat and drought in Australia, heavy rains later causing floods in the same areas, rivers flooding in South America, drought and heat in the United States and Europe, below normal rainfall in western and central Africa, monsoons in southeast Asia, heavy rains in Mexico and southern United States, hurricanes and cyclones, and record cold in November in the United States. UNEVEN PATTERN; THE 1982-83 SNOW SEASON,
D. M. Ludlum.
Weatherwise, Vol. 37, No. 1, p 20-23, February, 1984. 3 Fig.

Descriptors: *Weather, *United States, *Snow, Snow cover, Snow pack.

In the United States the snow season of 1982-83 was characterized by its uneveness. The most unusual early-season snowstorms occurred in central Wyoming where Lander measured a total of 32.9 inches, a new September record. The big snow scene in October shifted to the Black Hills of South Dakota. The heavy snow season got underway in November in the Sierra of California with 105 inches at Twin Lakes. El Paso recorded the most unusual December snows, with a total of 18.2 inches. Precipitation in New England was deficient, and January showed record warming trends in all the snow country. March of 1983 brought the biggest snows of the year to California and the season continued at a good rate into April. Very heavy wet snows fell at higher elevations of the West topped by a storm which left an estimated four feet in the Bearpaw Mountains of north central Montana. Winter totals for the Pacif
tains included 707 inches at Twin Lakes
nia, and 667 inches at Rainier Paradise,
ton. At Donner summit in the central S
season total exceeded all others in a reco
back to 1870. The snowpack disappeared
Lake on July 22 after 270 days with 1 inch
on the ground and at Rainier Paradise o
after 280 days with snow cover. (Baker-IV

rsion of a generalized method of estimating
ble maximum precipitation (PMP) is applied
catchments of four large dams in India. The
of a secure dam is high both in terms of
n life and in economic terms. Reliable esti-
of PMP are required in estimating the design
for spillways of large earth and rockfill dams.
ates of PMP obtained using the traditional
d of moisture maximization and storm trans-
on can be unreliable as highly efficient rain
may not be represented in the rainfall
ls of an area. Generalized methods of (calcu-
PMP are used to obtain reliable estimates of
and also to give estimates which are consist-
er a region. This is done by pooling together
rainfall data from a very large area. The
depths are normalized for such factors as
dew-point temperature, distance of the storm
he coast, topographic effects and any inter-
mountain barriers between the rainfall area
e moisture source. These normalized values
en be applied to any individual catchment,
ie appropriate adjustment factors. (Author's

s: *Diurnal variation, *Precipitation,
patterns, Probability, Seasonal variation,
Rainfall distribution, New England, New York, New Jersey, Pennsylvania.

The diurnal and semidiurnal variations of precipitation over the northeastern United States (New England, New York, New Jersey and Pennsylvania) are investigated using 25 years of hourly precipitation data for 271 stations. The hourly data were harmonically analyzed for all measurable precipitation events ranging upwards to amounts < 10.0 mm. Additionally, a regional probability of precipitation analysis was performed for homogeneously grouped stations. The winter season (November-March) displays a general early-to-mid-morning diurnal maximum for all measurable precipitation events across the Northeast with a shift to just before noon southward into Pennsylvania. For heavier precipitation events, much of the region retains the morning maximum, a notable exception being the northern mountains of New York and New England, where there is a late-evening maximum. The spring (April-May) season is quite similar to winter, although the diurnal amplitudes become weaker everywhere except from southeastern Pennsylvania, up across the New York City metropolitan area, and into southern New England, where a stronger early-morning maximum appears. Evidence for nocturnal activity is seen across western New York and Pennsylvania in the heavier precipitation category, possibly in association with stagnating warm fronts that seldom move eastward due to cold air damming in New England. Summer (June-August) features a prominent diurnal cycle at most inland locations for all precipitation categories. A strong 1800 LST maximum exists in western Pennsylvania, with a trend towards a later maximum as one moves eastward towards southern New England. Coastal stations and those along the shores of Lakes Erie and Ontario show a tendency towards nocturnal precipitation, as there appears to be a suppression of daytime convection due to the cooler ocean and lake waters. The autumn (September-October) season displays a return to a weaker diurnal pattern, similar to spring. The morning maxima return to most places, except in the mountainous areas, where late season convection tends to peak in the afternoon. The semidiurnal cycle is weak across all seasons and tends to reflect the influence of local circulations. The regional probability of precipitation analysis reveals that much of the interior northeastern United States, with the exception of western and central Pennsylvania, has maxima centered at 0300, 1000 and 1800 LST for all measurable precipitation events during the cool season. These maxima appear to be the result of a blend of synoptic scale and mesoscale forcing involving phenomena peculiar to the local geography. During the spring and summer the afternoon convective signal is most strongly evident inland. It is especially pronounced in western Pennsylvania where a further nocturnal springtime maximum is seen. Finally, an analysis of precipitation by day of the week and by day of the lunar synodic cycle is presented. No concrete evidence is found to support either signal. (Author's abstract)

EFFECTS OF DROP SIZE DISTRIBUTION TRUNCATION ON RAINFALL INTEGRAL PARAMETERS AND EMPIRICAL RELATIONS,
Clemson Univ., SC. Dept. of Physics and Astronomy.
C. W. Ulbrich.
Journal of Climate and Applied Meteorology, Vol. 24, No. 6, p 580-590, June, 1985. 9 Fig, 20 Ref. National Science Foundation grant ATM-8120686.

Descriptors: *Rain, *Drop size distribution, *Fluid drops, Statistical analysis, Disdrometers, Numerical analysis.

A description is given of a method of estimating the effects of truncating the raindrop size distribution (DSD) at lower and upper drop diameters D min and D max which assumes that the DSD can be approximated by a gamma distribution (including the exponential distribution). The method is used to investigate the effects of DSD truncation on rainfall integral parameters (e.g., reflectivity factor, liquid water content, etc.) and on empirical relations between pairs of these integral parameters. Tests of the theoretical predictions are performed using a set of drop size data collected with a Joss disdrometer. A brief description is also given of the use of the method to determine DSD truncation effects on precipitation parameters deduced from dual-measurement techniques. (Author's abstract)

FRACTAL PROPERTIES OF RAIN, AND A FRACTAL MODEL,
Etablissement d'Etudes et de Recherches Meteorologiques, Paris (France).
S. Lovejoy, and B. B. Mandelbrot.
Tellus, Vol. 37A, No. 3, p 209-232, May, 1985. 18 Fig, 1 Tab, 36 Ref.

Descriptors: *Fractals, *Rainfall, *Model studies, Simulation, Probability, Statistical studies, Spatial distribution, Temporal distribution, Rainfall distribution.

This paper amplifies upon earlier theories and observations by the authors, advances a probabilistic model of rain fields, and exhibits realistic simulations. The model is also compared with other approaches. The theory of fractals has been in part motivated by the Hurst effect, which is an empirical observation in hydrology and climatology. A fractal is an unsmooth shape that is scaling, that is, where shape appears unchanged when examined by varying magnifications. The study of fractals is characterized by the prevalence of hyperbolically distributed random variables, for which $Pr(U > u)$ varies directly as u to the -alpha where Pr is the probability that the value of the variable exceeds u, and alpha is a positive exponent. Lovejoy established the applicability of fractals in meteorology, by showing that cloud and rain areas project on the Earth along shapes whose boundaries are fractal curves, and that the temporal and spatial structure of rain is rife with hyperbolically distributed features. These observations, as amplified in this paper, set up the challenge of constructing fractal models with the observed properties. The models presented here belong to a very versatile family of random processes devised in Mandelbrot: fractal sums of (simple) pulses, or FSP processes. The simulations to be presented reveal that these processes involve a scaling heirarchy of 'bands', 'fronts', and 'clusters', as well as other complex shapes, none of which had been deliberately incorporated in the process. This very rich morphology and the related statistical distributions exemplify the power of simple fractal models to generate complex structures, and are in accord with the wide diversity of actual rainfall shapes. It is argued that this model already provides a useful context in which the basic statistical properties of the rainfield, including the relationship between the temporal and spatial structure, may be studied. SENSITIVITY OF AN ENERGY BALANCE CLIMATE MODEL WITH PREDICTED SNOWFALL RATES,
National Oceanic and Atmospheric Administration, Princeton, NJ. Geophysical Fluid Dynamics Lab.
K. P. Bowman.
Tellus, Vol. 37A, No. 3, p 233-248, 1985. 10 Fig, 2 Tab, 28 Ref, 1 Append. NSF grant ATM 8106800.

Descriptors: *Climate, *Energy balance, *Model studies, *Snowfall, Snow cover, Ice sheets, Solar radiation, Hydrologic cycle, Temperature, Water vapor, Atmospheric transport.

A two-level zonally-averaged seasonal energy balance model with separate land and ocean temperatures and an explicit surface energy budget is used

to study the effects of the snowfall rate of the extent of snow cover and ice sheets. Sensitivity experiments are performed both with and without ice sheets and with two different snowfall parameterizations. When snowfall rates are prescribed independent of latitude, higher snowfall rates increase the area of snow cover but reduce the sensitivity of the snow line to changes of the solar constant. To eliminate arbitrary assumptions about the snowfall rate, a relationship between the atmospheric transports of water vapor and sensible heat is derived and tested against observations. The relationship obtained is used to predict the meridional transport of water vapor in the model, from which the precipitation and snowfall are calculated. The response of the hydrologic cycle to changes of the solar constant is qualitatively similar to that found in general circulation models. The snow line is more sensitive with the predicted precipitation than with the prescribed precipitation because the predicted precipitation rate increases toward the equator. When ice sheets are included, they are larger than permanent snow cover under the same conditions because the cold surface temperatures at high elevations on the ice sheet inhibit melting. Feedback effects of the ice sheets are small, in part because they are limited to 30% of a latitude circle in this model. (Author's abstract)

GLOBAL STATUS AND TREND OF DESERTIFICATION,
United Nations Environment Programme, Nairobi (Kenya). Desertification Branch.
G. Karrar, and D. Stiles.
Journal of Arid Environments, Vol. 7, No. 4, p 309-312, 1984. 2 Fig.

Descriptors: *Desertification, *Drought, *International commissions, United Nations, Foreign aid, Erosion, Land use, Planning, Rainfall, Irrigation, Developing countries, Political aspects, Organizations.

Drylands are presently under stress to a degree perhaps unprecedented in history. High human and livestock populations growth, chronic drought and bad land-use practices in many areas have resulted in 75% of all the productive land within the world's drylands becoming desertified to some extent. A United Nations Conference on Desertification in 1977 formulated the Plan of Action to Combat Desertification (PACD). On all fronts, desertification has worsened since the conference. Land irretrievably lost to desert continues at 60,000 sq km/yr, while land rendered economically unproductive is showing an increase at 210,000 sq km/yr. Most responsibility for implementing the PACD at the national level rests with governments. UNEP (United National Environment Program) hoped to use the occasion of the 12th Governing Council and the presentation of the Executive Director's report on the General Assessment to stimulate renewed interest in the global problem of desertification. It is a problem which needs immediate, concentrated attention by the world's governments and international organizations. (Baker-IVI)

Descriptors: *Drought, *Crop yield, *Rajasthan, *India, Monsoons, Millet, Pulses, Rainfall, Aridity index.

Failure of the monsoon rains leading to drought conditions is common in Rajasthan State, India. The incidence and spread of drought over Rajasthan during the years 1972, 1974 and 1979, were analyzed on the basis of departures from the normal aridity index during different months of the southwest monsoon season. District averages of monthly rainfall for all the 26 districts in Rajasthan State were obtained from the daily rainfall records. The average rainfall in the State decreased by 32, 18 and 7% during the drought years 1972, 1974 and 1979, respectively. Consequently 84, 68 and 86% of the total area was affected by drought in the respective years. Productivity of pearlmillet and pulses was considerably affected by drought conditions. The impact of drought on the fall in productivity of these crops is more pronounced in western Rajasthan than in eastern Rajasthan. The decrease in yields during the three drought years varied from 61 to 92% in pearlmilet and 71 to 86% in the pulse crop. The variations in the productivity of the rainfed crops can be explained satisfactorily by the pattern of incidence and the spread of droughts. (Moore-IVI)

MODELLING ALPINE SNOW ACCUMULATION AND ABLATION USING DAILY CLIMATE OBSERVATIONS,
Canterbury Univ., Christchurch (New Zealand). Dept. of Geography.
R. D. Moore, and I. F. Owens.
Journal of Hydrology (New Zealand), Vol. 23, No. 2, p 73-83, 1984. 5 Fig, 2 Tab, 20 Ref.

Descriptors: *New Zealand, *Model studies, *Snow, *Ablation, Alpine regions, Air temperature, Mountains, Simulation, Precipitation, Altitude.

Modelled snow storage is compared to data from a snow course in the Craigieburn Range, and the utility and limitations of this approach are assessed for New Zealand conditions and data availability. Low-altitude precipitation measurements appear to provide a good index of high-altitude precipitation when averaged over the accumulation season. Snow storage was reasonably reproduced when temperatures measured at a site above the seasonal snow-line were used. The simulation quality was less satisfactory when low-altitude temperatures were used, because of marked and systematic deviations of the actual from the assumed lapse rate, and the consequent problem of distinguishing rain from snow. If no high altitude temperature measurements are available, the use of observations of storm snow-line elevations to determine the phase of precipitation may improve simulation quality. Application of these approaches should help to overcome lack of data on snow accumulation in mountainous areas of New Zealand. (Baker-IVI)

INTERNATIONAL PERSPECTIVE ON LARGE-SCALE SNOW STUDIES,
Agricultural Research Service, Beltsville, MD. Hydrology Lab.
A. Rango.
Hydrological Sciences Journal, Vol. 30, No. 2, p 225-238, June, 1985. 3 Fig, 2 Tab, 18 Ref.

Descriptors: *International commissions, *Snow, *Large scale studies, *Research priorities, Precipitation, Remote sensing, Policy making, Governmental interrelations, Political aspects.

Because of significant physical differences between snow and other naturally occurring substances, snow is not only a valuable resource but it also has significant large-scale effects on weather, climate and the hydrological cycle. A working group of the IAHS International Comission on Snow and Ice (ICSI) has recently reached certain conclusions regarding these effects. In order to study and model the large-scale effects of snow, the standardization of existing ground observation methods, the exploitation of new technologies such as remote sensing, and the systematic archiving of all data are necessary. Various research efforts and international activities have been identified which, when accomplished, should lead to improved unde ing and management of the large-scale ef seasonal snow cover. An international orga should take the lead in promoting an exch ideas, techniques, measurements, research and management strategies on large-scal studies. (Author's abstract)

Evaporation, Groundwater inflow, Saline
euterium, Recharge.

ome, situated in northern South Australia,
water only rarely, the last time being in
d 1973-74. Depth profiles of deuterium
ion, expressed as delta-values, have been
make point estimates of evaporation from
of the normally 'dry' Lake Frome. Values
e sites, varying between 90 and 230 mm/yr, have been used to obtain a relatively crude approximation for mean evaporation rate from the lake of 170 mm/yr. This estimate is lower than would be expected at first sight for an almost saturated sediment surface with a water table at about 300 mm in an environment where the evaporation rate from a Class A pan is 3200 mm/yr. Actual evaporation is reduced well below potential because the vapor pressure deficit between the atmosphere and water at the evaporating surface is reduced because this water is saturated with sodium chloride. Because the surface is almost white, it has an albedo much higher than that of a free-water surface. The total evaporative flux from the lake is estimated to be 4.6 x 10 to the 8th power cu m/yr. In periods of no surface water inflow to the lake this represents the groundwater inflow to the lake. Under steady state conditions, and assuming that the surface catchment and the groundwater catchment are identical, this corresponds to a mean recharge flux of about 1 mm/yr over the catchment. (Moore-IVI)

DIFFERENCES IN ANNUAL EVAPORATION BETWEEN GRAZED PASTURE AND EUCALYPTUS SPECIES IN PLANTATIONS ON A SALINE FARM CATCHMENT,
Commonwealth Scientific and Industrial Research Organization, Wembley (Australia). Div. of Groundwater Research.
E. A. N. Greenwood, L. Klein, J. D. Beresford, and G. D. Watson.
Journal of Hydrology, Vol. 78, No. 3/4, p 261-278, June, 1985. 8 Fig, 4 Tab, 5 Ref.

Descriptors: *Evaporation, *Eucalyptus trees, *Pastures, *Australia, Saline seeps, Leaf area, Interception, Stem flow, Land reclamation, Saline farm land.

Daily evaporation (including evaporation from the ground surface) from grazed annual pastures and from five species of Eucalyptus in two farm plantations (in Australia) was measured at regular intervals for a year. Leaf area of trees and pasture, and rainfall interception and stem flow by trees, were also measured. The trees were in their seventh year after germination. The site was a first-order catchment that had developed a saline seep midslope after the felling of the prior forest. One plantation was upslope, the other was immediately above the seep. The work is part of a salinity reclamation study based on increased evaporation through the strategic use of trees. Annual evaporation from pastures was 390 mm regardless of position in the landscape. Annual evaporation from trees upslope was 2300 mm for Eucalyptus maculata and 2700 mm each for E. globulus and E. cladocalyx. Values at midslope were 1600 mm for E. wandoo, 1800 mm for E. leucoxylon and 2200 mm for E. globulus. Expressed as a proportion of annual rainfall (680 mm), annual evaporation was 0.6 for pasture and ranged from 2.4 to 4.0 for trees while interception by trees ranged from 0.16 to 0.36, and stem flow was less than 0.02. Annual evaporation, but not interception, was correlated with leaf area. The application of these findings is discussed. It is concluded that the planting of discrete areas of trees has the evaporation potential to assist in reclamation of saline farm land in the southwest region of Australia and that some species are much more effective than others. SIMPLIFIED PROCEDURE FOR THE EVALUATION OF THE LAKE KINNERET EVAPORATION,
TAHAL-Water Planning for Israel Ltd., Tel-Aviv.
E. Simon, and F. Mero.
Journal of Hydrology, Vol. 78, No. 3/4, p 291-304, June, 1985. 4 Fig, 4 Tab, 10 Ref.

Descriptors: *Lake evaporation, *Lake Kinneret, *Israel, Hydrologic budget, Energy balance, Mass transfer, Meteorology, Air temperature, Water temperature, Evaporation.

Actual evaporation losses from lake surfaces can still not be determined by direct measurements. This presents a major problem to the planners, especially in cases as Lake Kinneret (Israel), where evaporation losses represent about 30% of its water budget. A description is given of the various approaches to find an optimal method for the quantitative estimation of evaporation losses from this lake, to enable reliable water-budget calculations and also to serve as a tool for the various water allocation models for long-range planning, now under development. Past experience shows that the best evaporation estimates can be obtained by the energy balance and the mass transfer methods, widely used all over the world. In this case, two micro-meteorological stations were installed on the up-wind western and the down-wind eastern shore of the lake. The big mass of the accumulated data has been carefully analyzed, and served as a basis for the various theoretical and more or less empirical approaches to obtain the desired optimal estimate of lake evaporation losses. Another problem to be solved was to find simpler, more easily obtainable data (as air and water temperatures, etc.), to serve as long-term evaporation estimator, to permit reconstruction of long-term series of Lake Kinneret water balances, to permit optimized use of the available water resources originating from the Jordan River and the direct drainage area of this lake. The various estimation methods, discussed in this paper were calibrated and compared to the now used energy balance method, considered as the most reliable approach for the evaporation measurements. During the process of these analyses, some doubts were raised as to the reliability of frequently used methods for the elusive estimate of evaporation losses. (Author's abstract)

CALCULATING THORNTHWAITE AND MATHER'S ACTUAL EVAPOTRANSPIRATION USING AN APPROXIMATING FUNCTION,
Oak Ridge National Lab., TN. Environmental Sciences Div.
J. Pastor, and W. M. Post.
Canadian Journal of Forest Research, Vol. 14, p 466-467, 1984. 1 Fig, 6 Ref. DOE contract W-7405-eng-26.

Descriptors: *Evapotranspiration, *Water loss, *Soil water, Precipitation, Temperature effects, Water storage.

Soil water storage is related to a maximum storage value (field capacity) and accumulated potential water loss through a simple negative exponential function. This formula summarizes 10 tables from the Thornthwaits and Mather (Publications in Climatology, 10: 183-311, 1957) needed to calculate actual evapotranspiration. Values predicted by this formula and the Thornthwaite and Mather's tabulated values are compared. Discrepancies between tabulated and predicted values occurred largely due to the fact that the equation is a continuous function while the tables are step functions. (Baker-IVI)

2E. Streamflow and Runoff

SOUTHLAND FLOOD OF JANUARY 1984,
Southland Catchment Board, Invercargill (New Zealand).
D. C. Riddell.
Journal of Hydrology (New Zealand), Vol. 23, No. 2, p 120-129, 1984. 6 Fig, 1 Tab, 3 Ref.

Descriptors: *Rainfall, *Southland, *New Zealand, *Waihopai River, *Floods, Storm runoff, Water levels, Probable maximum precipitation, Flood hydrographs, Flood flow.

Nine automatic raingauges and more than 100 manual gauges gave an excellent record of the storm rainfall which caused the floods of January 1984 in Southland and caused extensive damage. River flows and lake levels were recorded at 17 sites. Over the 18 hours which the storm lasted, heavy rainfall was associated with fronts in an extremely deep and humid northwesterly airflow. The estimated probably maximum flood for the

Waihopai River which flows through Invercargill is twice the size of the January 1984 flood which reached 112 times mean flow. Being far larger than any other storm experienced in recent times, the 1984 storm provided an opportunity for assessing the likely probable maximum precipitation for the Invercargill region and particularly for the Waihopai River catchment. Temporal distribution of the January 1984 storm rainfall was similar to that normally assumed for the probable maximum precipitation, so a probable maximum flood hydrograph for the Waihopai River was derived by scaling the ordinates of the January flood hydrograph by the ratio of the probable maximum direct runoff to the January runoff. If 10% of the probable maximum precipitation were retained in storage, a direct runoff of 21 mm would be expected. This is twice the January 1984 flood runoff. With baseflow this would result in a probable maximum peak flow of 580 cu m/sin the Waihopai River, a specific discharge of 3.6 cumecs per square kilometer. (Baker-IVI)

PROBABILITY-DISTRIBUTED PRINCIPLE AND RUNOFF PRODUCTION AT POINT AND BASIN SCALES,
Institute of Hydrology, Wallingford (England).
R. J. Moore.
Hydrological Sciences Journal, Vol. 30, No. 2, p 273-297, June, 1985. 10 Fig, 33 Ref.

Descriptors: *Statistical analysis, *Runoff forecasting, *Hydrologic models, *Rainfall-runoff models, Infiltration capacity, Storage capacity, Overland flow.

The probability-distributed principle in basin-scale hydrology considers the frequency of occurrence of hydrological variables (model inputs, parameters or elements) of certain magnitudes over the basin without regard to the location of a particular occurrence within the basin. The random assemblage of different parts is considered more important than the relation of the parts, one to another. Rainfall-runoff models based on probability-distributed infiltration capacity and storage capacity concepts, and which generate runoff according to Hortonian and saturation overland flow mechanisms respectively, are distinguished. Two types of probability-distributed storage capacity model are identified, one based on an assumption that storage elements at points in the basin respond independently of their neighbors, and the other where storage elements interact so as to equalize the depth of stored water over the basin. Allowing redistribution of water leads to simplification of the model equations. The probability-distributed principle is also used to represent the process of water translation through the basin. Interpretation of the instantaneous unit hydrograph as a probability density function of translation time is demonstrated and the inverse Gaussian density proposed as a suitable functional form on physical grounds. RIVER RECESSION ANALYSIS IN THE OPERATIONAL MANAGEMENT OF LAKE ABSTRACTION,
S. Walker, and D. Pearson.
Journal of the Institution of Water Engineers and Scientists, Vol. 39, No. 3, p 244-253, June, 1985. 7 Fig, 4 Ref.

Descriptors: *Water level fluctuations, *Lakes, *Water management, Mathematical equations, Water level, Forecasting, Stream flow, Rivers.

The need to obtain reliable estimates of the likely changes in stream flow with time has led to a reappraisal of the methods available for analyzing flow data. The need also to include a stochastic component in the description of the way in which such data arise leads to some problems, but the developed techniques have been found to provide a reasonable solution to them. The methods are attractive, as they make no assumptions about the relationship between successive daily flows and hence may be applied in a wide range of situations. Some care is required when analyzing data with a high level of observational noise and for which recession rate varies markedly with flow. The search for more flexible techniques was justified by the analysis of flow data from Windermere and Ullswater. Here, recession rate varied with flow, and the relationship between them was different with and without abstractions. Changes in recession rate with flow were also observed on the river Derwent, though these were of a smaller order than those observed on the rivers controlled by lakes. A comparison between the recession curve for the unregulated flow in the river Derwent and the curves for Windermere and Ullswater in the no-pumping case is presented. The curves for Ullswater and the Derwent are similar, showing a steady quickening of recession rate as flow increases. This is the shape which can be expected for an uncontrolled river. In comparison, the curve for Windermere is much flatter. This is reasonably explained by difference in physical characteristics of the outlets to the lakes. The recession curves for Windermere have been used to construct a diagram showing the number of days for which pumping is likely to be sustained before the flow falls below a prescribed flow level. This is now being used as an aid in the everyday operation of the pumping station, and proves a practical example of the value of obtaining reliable estimates of recession factors for use in the management of lake and river abstraction systems. TURBULENT FLOWS OVER A WAVY BED,
Delaware Univ., Newark. Ocean Engineering Program.
N. Kobayashi, and O. S. Madsen.
Journal of Geophysical Research, Vol. 90, No. C4, p 7323-7331, July, 1985. 3 Fig, 1 Tab, 24 Ref.

Descriptors: *Turbulent flow, *Wavy beds, *Hydrodynamic models, Model studies, Shear stress, Boundary conditions, Ripples, Hydraulics, Hydrodynamics, Fluid mechanics.

A hydrodynamic model was developed for the calculation of shear stress and pressure along a sinusoidal boundary that is fixed or propagating very slowly in a wide rectangular open or closed channel. The model uses curvilinear coordinates that follow the wavy boundary, and it is similar to that for two-dimensional wavy boundary flows of infinite extent proposed by Benjamin except that the present model takes account of turbulent stresses on the basis of the turbulent eddy viscosity concept employed by Hussain and Reynolds. The compact analytical expressions for the perturbed shear stress and pressure on the wavy boundary are derived for the cases of hydraulically smooth turbulent and fully rough turbulent flows. The developed model is shown to be in good agreement with the experiments conducted by Zilker et al. The developed hydrodynamic model is applied to the problem of the formation of ripples in erodible channels by Kobayashi and Madsen. (Author's abstract)

TURE REGIME IN WATER BODIES OLGA DELTA UNDER REGULATED CONDITIONS,
Reserve (USSR).
kov, and A. V. Moskalenko.
ources, Vol. 11, No. 4, p 347-354, July-84. 4 Tab, 6 Ref. Translated from esursy, No. 4, p 95-99, July-August,

: *Water temperature, *Volga Delta, unoff, Temperature effects, Weather, rological regime, Swamps, Lakes.

perature is one of the important ele- e hydrologic regime which has a con-siderable effect on natural processes in water bodies of the Volga delta (USSR). The temperature regime of various water bodies of the delta is different and depends on the temperature of the water arriving there from the Volgograd reservoir, general weather conditions of the region, daily variation of the air temperature in the delta, depths of the water body, flowage, and its overgrowth by aquatic vegetation. In the shallow channels criss-crossing the delta the flowage is slightly weaker than in the Volga branches, the water temperature is higher than in the Volga but lower than in the backswamp and delta lakes. Heated water can flow into such shallow channels from the back swamps and delta lakes. The temperature regime of the backswamps and delta lakes in the lower part of the Volga-Aktuba floodplain differs somewhat from the temperature regime of the backswamps and lakes of the lower reaches of the delta. This is related to the fact that in the floodplain flooding of the backswamps and lakes occurs rapidly, primarily with cold surface waters of the Volga; the depths are considerably greater; flowage sets in at the start of their flooding; the current speeds are considerable; owing to the absence of dense aquatic and terrestrial vegetation heating of the water column in them occurs gradually and uniformly from the surface to the bottom. The rise of water temperature in water bodies of the delta after the ice period occurs at different times throughout its territory. As a result of regulating the Volga runoff, considerable changes occurred in the characteristics of the temperature regime of the delta water bodies. An increase of the water temperature in the delta water bodies in the fall-winter period already has an effect on the dynamics of the hydrologic and geomorphologic processes occurring in them. The current state of the thermal regime should be taken into account when planning and conducting measures to increase the biological productivity of the delta water bodies. (Baker-IVI)

FINITE AMPLITUDE WAVES IN STRATIFIED TWO-PHASE FLOW: TRANSITION TO SLUG FLOW,
California Univ., Santa Barbara.
R. Ahmed, and S. Banerjee.
AIChE Journal, Vol. 31, No. 9, p 1480-1487, September, 1985. 8 Fig, 13 Ref. NSF grant CP-81-12667.

Descriptors: *Slug flow, *Two-phase flow, *Mathematical equations, Density, Velocity, Waves, Schrodinger equation, Stratified flow, Wave amplitude.

In horizontal two-phase flow, phases stratify due to density differences if the velocity difference between the phases is small relative to the phase velocities. as the velocity difference between the phases is increases, waves appear on the initially smooth interface but the phases remain distinctly separated. At sufficiently high velocity differences interfacial waves grow rapidly, tending to block the flow, i.e., they are swept up to form slugs. A perturbation technique based on the method of multiple scales is used to solve the system of equations governing finite amplitude waves at the interface between two bounded fluids. This method allows the separation of the system into two parts: the rapidly varying phase of the disturbances, and the slowly varying amplitude. The complex system of equations governing the modulation of the wave amplitude can be reduced to a nonlinear Schrodinger equation. Nonlinear instability is essentially determined by the signs of two coefficients in the Schrodinger equations, leading to an analytically established criterion for the growth of finite-amplitude waves at the interface between two bounded flowing fluids. The predictions made by this study are in reasonable agreement with existing experimental results and appear to provide a theoretical framework for interpreting experiments on transition from stratified to slug flow. EXPERIMENTAL MEASUREMENT OF CHANNELING OF FLOW IN POROUS MEDIA,
Cold Regions Research and Engineering Lab., Hanover, NH.
J. L. Oliphant, and A. R. Tice.
Soil Science, Vol. 139, No. 5, p 394-399, May, 1985. 3 Fig, 2 Tab, 10 Ref.

Descriptors: *Soil water, *Channeling, *Porous media, *Permeability coefficient, Unsaturated flow, Montmorillonite, Clays, Hydraulics, Silt.

By comparing experimental measurements of the hydraulic conductivity and the effective self-diffusivity of water in porous media, a channeling parameter, c, is defined. This parameter measures the degree of division of flow paths in the media, but does not depend on the tortuosity of the paths or surface effects on the viscosity of the water. Values of c are obtained for Na-saturated montmorillonites containing from 0.82 to 7.7 g of water per g of clay and for Fairbanks silt containing from 0.135 to 0.23 g of water per g of silt. Values for the montmorillonites remain relatively close to the theoretically predicted value of 1/3 of all water contents, indicating maximally divided flow paths. Values for the silt vary from 100 to over 2000, indicating highly channeled flow. (Author's abstract)

ELECTRICAL RESISTIVITY FOR ESTIMATING GROUND-WATER RECHARGE,
Nebraska Univ.-Lincoln. Dept. of Civil Engineering.
W. E. Kelly.
Journal of Irrigation and Drainage Engineering, Vol. 11, No. 2, p 177-180, June, 1985. 2 Fig, 7 Ref. NSF grants GK-42130 and ENG 78-19408.

Descriptors: *Groundwater recharge, *Resistivity, *Unsaturated flow, Permeability coefficient, Vadose water, Hydrogeology.

Estimates of recharge rates from surface resistivity measurements should be possible under favorable conditions. Electrical properties of unsaturated soils can be characterized by a form of Archie's law. Differences in resistivity are primarily due to differences in degree of saturation with fine-grained sediments tending to occur in situ at lower resistivities than coarse sediments which occur at lower degress of saturation. On a relative basis, higher transverse resistances would reflect sites more favorable for recharge. Estimates of transverse resistance may be made without interpreting sounding curves in some cases. When sounding curves can be completely interpreted, the resistivity of the vadose zone can be estimated. The resistivity of this layer will be an average transverse resistivity which should correlate with the average hydraulic conductivity of the vadose zone during recharge. Field data under a variety of geohydrological conditions are needed, along with lab work on the electrical properties of unsaturated soils and a study of the geometric effects mentioned. This information would provide a sounder basis for applying the surface resistivity in recharge studies. (Baker-IVI)

THERMAL INFRARED DETECTION OF SUBMARINE SPRINGS ASSOCIATED WITH THE PLYMOUTH LIMESTONE,
Plymouth Polytechnic (England). Dept. of Environmental Sciences.
I. S. Roxburgh.
Hydrological Sciences Journal, Vol. 30, No. 2, p 185-196, June, 1985. 11 Fig, 1 Tab, 15 Ref.

Descriptors: *Infrared imagery, *Submarine springs, *Plymouth Limestone, *Devon, *England, Remote sensing, Springs, Groundwater, Limestone, Coastal aquifers, Geomorphology, Geohydrology.

The Plymouth Limestone is the most westerly of a number of separate carbonate outcrops occurring in South Devon, England. In the absence of land-based springs and in the presence of a groundwater gradient which falls seawards from the Upper Devonian slates to the limestone, it is possible that

groundwater discharge from the Plymouth Limestone is taking place through a number of coastal and submarine springs in Plymouth Sound. Freshwater groundwater within the Plymouth Limestone can be shown to be in hydraulic continuity with the marine waters of Plymouth Sound. Fresh groundwater discharges from the limestone in the form of submarine springs can be detected on the basis of temperature differences between the fresh groundwater and the marine waters using an aircraft-mounted thermal infrared linescanner. Analysis of the thermal data is improved and aided by the use of the GEMS color contouring analysis facility. (Collier-IVI)

APPROPRIATE MONITORING TECHNIQUES USING BOMB TRITIUM AND OTHER GEOCHEMICAL PARAMETERS IN HYDROGEOLOGICAL INVESTIGATIONS,
Anambra State Univ. of Technology, Awka (Nigeria). Water Resources and Environmental Pollution Unit.
B. C. E. Egboka.
Hydrological Sciences Journal, Vol. 30, No. 2, p 207-224, June, 1985. 7 Fig, 3 Tab, 40 Ref.

Descriptors: *Tritium, *Isotope studies, *Geochemistry, *Geohydrology, Water chemistry, Monitoring, Radioisotopes, Groundwater movement, Groundwater dating.

Since the atmospheric nuclear tests in 1953, precipitation has contained concentrations of bomb tritium (H-3) higher than the H-3 naturally deposited prior to 1953; consequently, H-3 has been used to investigate groundwater flow systems. It is a tracer for pre-1953 groundwater. A critical review of earlier uses of bomb tritium spotlights problems in its applications that may result in erroneous interpretations. The old monitoring technique using boreholes causes mixing of groundwaters of different age zones. In this study, the mixing problem is overcome by using modern monitoring devices of multi-level samplers and bundle piezometers that yield groundwater samples of small volumes at closely-spaced intervals. The old method may be used to determine recharge and discharge areas of aquifers and used where pollution poses no serious threat. Otherwise, the major pumpage of the aquifer distorts and reverses flow directions, causes mixing of different waters and may spread the pollutants. The disadvantages of the modern method include its restricted use in shallow aquifers and porous media. Case studies for use of tritium as an identifier were conducted at: an abandoned landfill site at the Canadian Forces Base, Borden, Canada; at the Whiteshell Nuclear Research Establishment, Pinawa, Canada; and at the Greenbrook Well Field in Kitchener, Ontario, Canada. The use of isotopes in hydrological studies in Africa is discussed. (Collier-IVI)

DECIPHERING HYDROLOGICAL SYSTEMS BY MEANS OF GEOCHEMICAL PROCESSES,
Geological Survey, Reston, VA.
B. B. Hanshaw, and W. Back.
Hydrological Sciences Journal, Vol. 30, No. 2, p 257-271, June, 1985. 1 Fig, 42 Ref.

Descriptors: *Geochemistry, *Geohydrology, *Groundwater, *Physicochemical characteristics, Carbonate rocks, Aquifers, Saline-freshwater interfaces, Calcite.

The distribution of permeability and chemical character of groundwater in carbonate aquifers is significantly influenced by the many diagenetic processes and reactions that occur in the early development of these rocks. Many of these diagenetic processes occur in the transition zone formed as the carbonate sediments emerge from the marine environment and become fresh-water aquifers. Analyses of trace elements and isotopes indicate that calcite cements and dolomites are formed in this groundwater mixing zone. Reverse reactions such as mineral dissolution and dedolomitization occur in carbonate aquifer systems. The geochemical reactivity of the fresh-water/salt-water mixing zone results from the nonlinearity of geochemical parameters as a function of ionic strength and causes extensive dissolution in coastal carbonate rocks. Interpretation of geochemical reactions and isotopic composition of groundwater provides a method to determine hydrological parameters such as porosity, hydraulic conductivity, and groundwater flow rates. This geochemical method is largely independent of the more conventional approach of determining these parameters by an evaluation of physical properties of aquifer systems. (Author's abstract)

WATER FLOW AND SWELLING PRESSURE IN NON-SATURATED BENTONITE-BASED CLAY BARRIERS,
Luleaa Univ. (Sweden).
L. Borgesson.
Engineering Geology, Vol. 21, No. 3/4, p 229-237, June, 1985. 9 Fig, 5 Ref.

Descriptors: *Bentonite, *Groundwater barriers, *Swelling pressure, Permeability, Water flow, Barriers, Groundwater management, Groundwater pollution, Model studies.

Experiments were devised to determine the water uptake of 10 and 20% bentonite-sand mixtures and of 100% pure bentonite. The swelling pressure situation in an unsaturated clay barrier is very complex especially when the degree of saturation varies through the barrier, and when the access to water is restricted. A piece of bentonite can be highly saturated, and yet it will not exert any pressure on a surrounding stiff material, if it has no further access to water, and if it has been allowed to swell enough to transfer the pressure to something that might be seen as a negative pore pressure. It is necesary to find the influence of the degree of saturation on the swelling pressure in a small clay element, to be able to estimate the pressure in a more complex situation. The swelling pressure reaches a peak value after a relatively short time and then approaches a slightly smaller constant value. The peak value is probably due to either released elastic stresses in the sample, or to the fact that the degree of saturation is very high near the water inlet at the beginning of the test, before the water content is equalized. An equation is derived which serves as a useful model to describe water flow, if there is no temperature gradient. The water diffusion constant in this equation must be determined using the correct initial water content. The model gives better results if the material is partly saturated, than if it is dry. The swelling pressure is a linear function of the degree of saturation. (Baker-IVI)

CARBONATE CHEMISTRY OF RECENT CHALK GROUNDWATER IN A PART OF EAST ANGLIA, U.K.,
Birmingham Univ. (England). Dept. of Geological Sciences.
J. A. Heathcote.
Journal of Hydrology, Vol. 78, No. 3/4, p 215-227, June, 1985. 2 Fig, 3 Tab, 28 Ref.

Descriptors: *Groundwater, *Carbonates, *Chalk Aquifer, *England, Aquifers, Alkalinity, Hydrogen ion concentration, Carbon radioisotopes, Carbon dioxide, Dissolution, Chemical properties.

An example of apparent open-system dissolution is described from a region where a limestone aquifer is recharged through thick calcareous soils developed on till. Groundwaters in the area have higher alkalinities and lower pH-values than are generally reported for carbonate terrains, apparently as a consequence of open-system dissolution. However, limited C-13 isotope data are incompatible with this conclusion, indicating that exchange with the gas phase does not control the isotope chemistry and therefore that the system is isotopically closed. This paradox can be resolved if the dynamics of the system are considered; it is shown that back-diffusion of gas from the solution to the gas reservoir is prevented and therefore isotopic equilibrium between gas and solution is not achieved. Isotope data also show that limited transfer of carbon between soil water and soil calcite occurs. (Author's abstract)

ndwater situations are considered in the Indian Subcontinent. Particular given to the differing types of wells s, the estimation of recharge, and the important features of aquifers. A discussion is also presented of problems that have arisen during exploitation of groundwater including over exploitation, waterlogging and saline intrusion. As no two aquifers are alike, the approach must be varied for each. Although routine field investigations are needed for each study, there are usually certain key features that need to be identified before an adequate understanding can be gained. Identifying the key features is usually the difficult part of the study. In the Lower Mersey Sandstone aquifer it was important to identify the following consideration: before significant abstraction occurred there were many active springs; the actual recharge was less than the potential recharge due to the influence of the drift cover; the ingress of saline water from the Mersey Estuary allowed fresh water to be released for abstraction; hydrochemical information usually reflected conditions in the aquifer several hyundreds of years ago. For the Mehsana area aquifer the following features appear to be significant: only small quantities of water can move laterally through the aquifer; significant verical flow is occurring through the clay layers; and leakage through the beds of canals and water courses is likely to produce a significant increase in the recharge. In a regional groundwater study it becomes important to attempt to fit together the various aspects throughout the study. (Baker-IVI)

Descriptors: *Aquifer characteristics, *Hydraulic properties, *Electrical properties, Groundwater, Model studies, Hydrologic models, Groundwater flow.

Factors affecting relations between the geoelectric and hydraulic properties of aquifers are considered. The reliability of relations between electrical and hydraulic aquifer parameters depends primarily on two factors: the character of the material-level relationship; and the mutual relation between the direction of groundwater flow, layering and the hydrogeophysical conditions in the aquifer. The sources of errors in determining the basic geoelectric and hydraulic parameters in a set of measurements were analyzed. The necessity of applying a statistical criterion for determining the minimum number of parametric points was stressed. Both direct and inverse material-level relationships can exist depending on the rock type and the character of the hydraulic conductivity. Inverse relationships can be expected when porosity controls variations in hydraulic conductivity and other factors such as grain size, sorting, and clay content are relatively constant. Direct relationships appear to be controlled by inverse correlations between grain size and porosity or inverse correlations between clay content and hydraulic conductivity. A general hydrogeophysical model was used to demonstrate that at the aquifer scale a variety of relations may be expected. (Baker-IVI)

Descriptors: *Aquifers, *Pumping tests, *Parameter identification, Optimization, Permeability coefficient, Storage, Specific yield, Sensitivity analysis, Least squares method.

A method is presented for identification of parameters in unconfined aquifers from pumping tests, based on the optimization of the objective function using the least squares approach. Four parameters are to be evaluated, namely: the hydraulic conductivity in the radial and the vertical directions, the storage coefficient and the specific yield. The sensitivity analysis technique is used for solving the optimization problem. Besides eliminating the subjectivity involved in the graphical procedure, the method takes into account the field data at all time intervals without classifying them into small and large time intervals and does not use the approximation that the ratio of the storage coefficient to the specific yield tends to zero. Two illustrative examples are presented and it is found that the parameter estimates from the computational and graphical procedures differ fairly significantly. (Author's abstract)

In order to have a quick appraisal of the potential of an aquifer for meeting the irrigation needs of small farms and for supplying drinking water in the hard rock terrains of South India, short duration pump tests are carried out. A reliable estimate of hydrogeologic parameters was obtained through a pump test provided the recovery rate prior to the test is fed into a numerical model used for the interpretation of the data. In order to account for the effect of incomplete recovery it is necessary to observe not only the water level variations prior to the onset of pumping but also during the post pumping phase until the recovery is nearly complete for a correct interpretation of pump test data to be made. An appreciable aquifer response is observed only during recovery. The data on the recovery phase of the pump test are, therefore, necessary for the data analysis using the numerical method. Particularly the later portion of the recovery phase is more important, as the effect of prepumping incomplete recovery is pronounced in the latter portion only. (Baker-IVI)

Two methods were tested for their suitability to provide improved estimates of recharge in the region of eastern Long Island (New York). The two methods tested consist, first, of measuring recharge with a direct application of Darcy's law in the vadose zone and, second, of calculating recharge by closure of the hydrologic budget equation with evaporation computed from micrometeorologic data. The recharge figure, now in general use, of 50% of the annual precipitation is a long-term average at best. The measurements of recharge, which were performed during a three-

year period, showed that the vertical flux past the 1 m depth was strongly dependent on both the time of the year and the precipitation amount. In late fall, winter and early spring a high percentage of the precipitation became recharge. During the summer months there was a small net upward movement of water past the 1 m depth. Precipitation during these months did not contribute to the annual recharge. It may be concluded from these measurements that in order to estimate recharge, special attention should be given to precipitation during the winter months. A better estimate for annual recharge than the current 50% of annual precipitation might be to take approximately 75-90% of the precipitation from October 15 until May 15. The two methods used for estimating recharge were labor intensive and required experienced technicians. Currently, one method cannot be recommended above the other. Both methods give a good estimate during the year except for the winter. The closure method using micrometeorological data gives a slightly higher estimate than the direct measurement method based on Darcy's law. (Author's abstract)

A dense fluid in an unconfined aquifer is usually removed by pumping a recovery well screened in the region of the aquifer occupied by the fluid. For many problems, the transition zone separating the dense fluid from the overlying water can be modeled as a sharp interface. When the pumping begins, the interface is drawn downward, allowing water to enter the well. The recovery process is improved if a second well is drilled and screened in the zone occupied by the water. The simultaneous pumping of water tends to cause the interface to move upward, allowing the dense fluid to be recovered at an increased rate without water entering the recovery well. The boundary integral equation method (BIEM) is used to solve the problem of the response of a dense fluid near a recovery well in a ground-water aquifer. The axisymmetric problems considered here are time-dependent and involve a nonlinear boundary condition along the free surface, as well as a nonlinear, moving interfacial boundary. The entire boundary, including the moving boundaries, are discretized into axisymmetric finite elements for evaluating the required boundary integrations. Numerical examples include pumping both fluids simultaneously as well as separately. The model is used to illustrate the design of a recovery system for the efficient removal of the dense fluid. Tracer tests in natural fissures performed in the laboratory are analyzed by means of fitting two different models. In the experiments, sorbing and nonsorbing tracers were injected into a natural fissure running parallel to the axis of a drill core. The models take into account advection, dispersion, diffusion into the rock matrix, and sorption onto the surface of the fissure and on the microfissures inside the matrix. For the second mechanism, one of the models considers hydrodynamic dispersion, while the other model assumes channeling dispersion. The models take into account time delays in the inlet and outlet channels. The dispersion characteristics and water residence time were determined from the experiments with nonsorbing tracers. Surface and volume sorption coefficients and data on diffusion into the rock matrix were determined for the sorbing tracers. The results are compared with values independently determined in the laboratory. Good agreement was obtained using either model. When these models are used for prediction of tracer transport over larger distances, the results will depend on the model. The model with channeling dispersion will show a greater dispersion than the model with hydrodynamic dispersion, assuming constant dispersivity. (Author's abstract)

The problem of abstraction from a well penetrating a two-layered confined aquifer, each layer being independently homogeneous, isotropic, and artesian, is considered. Three components of the total abstraction are identified: the concentration from well storage and contributions from flow in each of the aquifer layers. Analytical expressions were derived for the three components; the expressions were evaluated numerically for different parameter sets in order to investigate the transient variation in the relative importance of the components. In the initial stages of pumping, well bore storage is the dominant factor, but the contribution falls effectively to zero as abstraction progresses. The length of time during which well bore storage provides a significant proportion of the total flow is dependent on the aquifer parameters as well as on the screen and casing radius. Reduction of the screen radius results in increased drawdown and a small increase in the importance of well bore storage during the early stages of pumping. In all cases, after a sufficiently long time of pumping, the aquifer flow contribution are divided in the same proportion as the transmissivities of the two layers. (Moore-IVI)

Water Resources, Vol. 11, No. 3, p 185-191, May-June, 1984. 5 Fig, 16 Ref. Translated from Vodnye Resursy, No. 3, p 23-29, 1984.

Descriptors: *Groundwater level, *Seepage, *Diffusion, *Hydrodynamics, Porous media, Convection, Anisotropy, Mathematical equations.

The problem of predicting the groundwater level is becoming ever more urgent in connection with the increasing anthropogenic impact on rivers and subsurface waters. Transfer of part of the runoff from one river basin to another and the creation of reservoirs and other hydraulic structrues is leading to a change in the paramters of flow which in turn causes a change in the groundwater level of adjacent territories. Few investigations have been performed in which fluid flow in inhomogeneous media is studied. This work is a further development of the hydrodynamic problem of seepage and convective diffusion for the case of inhomogeneous and anisotropic media. Examples are given which demonstrate how important the characteristics of a porous medium are. Schematization and assumption of physicochemical paramters as constant are not always valid. (Baker-IV)

FLOW OF A WELL IN AN INHOMOGENEOUS LAYERED ARTESIAN AQUIFER,
N. N. Lapshin.
Water Resources, Vol. 11, No. 3, p 192-203, May-June, 1984. 2 Fig, 12 Ref. Translated from Vodnye Resursy, No. 3, p 30-43, May-June, 1984.

Descriptors: *Aquifer characteristics, *Wells, Water flow, Groundwater movement, Artesian wells, Permeability, Flow rate, Water table, Hydrogeology.

Inhomogeneous layered media with complete consideration of two-dimensionality in the section of the groundwater flow in each of the layers composing the aquifer were studied theoretically. An artesian aquifer is examined which consists of two zones of different permeability. The length of the filter of the pumping well amounts to only part of the thickness of one of the layers of the two-layer aquifer. The main hydrogeologic parameters of a two-layer aquifer to be determined when conducting experimental seepage flow studies are the total value of transmissivity T and pressure conductivity factor, as well as the permeability coefficients of the layers composing the aquifer. It is necessary to determine these indices considering the main properties of groundwater flow during pumping in inhomogeneous aquifers. Flow imperfection of wells due to partial penetration in an inhomogeneous two-layer aquifer is determined to a considerable extent by the pressure conductivity factor. (Baker-IVI)

Descriptors: *Drawdown, *Groundwater, Water level, Mathematical equations, Safe yield, Water management, Irrigation water.

The existing methods of calculating the drawdown of the level (head) of groundwaters with periodic withdrawal are based on representing the withdrawal graph in the form of several steps. Random variations in the times of flushing, water spreading, and crop irrigations result in the form of the average long-term graph of the variation of ground water withdrawal for irrigation being rather smooth. The value of the lag depends on the relationship of the values of the maxima of withdrawal and duration of the time interval between them. The lags between the peak values of withdrawal and drawdown, which under certain conditions reach several months, can have a substantial effect on estimating the safe yield for irrigation. The value of the permissible drawdown assigned on the basis of thickness of the aquifer is not an exactly determined constant, but varies within certain limits. Consideration of the displacement of the peak values of drawdown with respect to the peak of withdrawal when estimating the safe yield can be expressed in an increase of the calculated values of the permissible drawdown to its upper limit. In certain cases, this value can probably be greater, taking into account that a brief drop of the level below the permissible value will occur in a period when the rate of withdrawal is substantially less than the peak value and probable disconnection of part of the wells will not lead to so substantial a complication of the water management situation as would occur at the height of crop irrigation. USES AND ABUSES OF WASTEWATER INJECTION WELLS IN HAWAII,
Hawaii Univ. at Manoa, Honolulu. Water Resources Research Center.
F. L. Peterson, and J. A. Oberdorfer.
Pacific Science, Vol. 39, No. 2, p 230-240, 1985. 7 Fig, 2 Tab, 15 Ref.

Descriptors: *Injection wells, *Wastewater disposal, *Hawaii, Domestic wastewater, Well clogging, Geohydrology, Nitrogen gas, Injection well capacity, Particulate matter, Microorganisms.

During the past two decades in Hawaii, more than 500 injection wells for the disposal of domestic sewage wastewater have been constructed and operated. Thus far, contamination of potable groundwater supplies has not been a problem. Many of the injection wells, however, have not performed as designed, and aquifer clogging and reduced injection capacity have produced numerous well failures resulting in public health, legal, and financial problems. Factors most commonly responsible for the well problems have been unfavorable hydrogeology, underdesign of injection well capacity, poor effluent quality, and lack of injection well maintenance. Detailed study of clogging mechanisms in the immediate vicinity of injection wells suggests that binding of pore spaces by nitrogen gas is the most important cause of aquifer clogging. Other clogging mechanisms also operating are filtration of solid particles and growth of microorganisms. (Author's abstract)

GROUND-WATER RESOURCES OF TOWNER COUNTY, NORTH DAKOTA,
Geological Survey, Bismarck, ND. Water Resources Div.
P. G. Randich, and R. L. Kuzniar.
Available from OFSS, USGS Box 25425 Lakewood, CO 80225. North Dakota State Water Commission County Ground-Water Studies 36 and North Dakota Geological Survey Bulletin 79, Part III. 26 p, 5 fig, 3 tab, 51 ref.

Descriptors: *Water resources, *Groundwater, *Aquifers, Transmissivity, Recharge, Water use,

Chemical properties, Potential yield, Storage, Towner County, North Dakota.

Large quantities of water can be obtained from glacial-drift aquifers in Towner County, North Carolina. Glacial-drift aquifers occur as saturated sand and gravel deposits that range in thickness from 4 to 287 feet. These aquifers underlie about 550 square miles and contain approximately 2.8 million acre-feet of available ground water. Potential well yields range from 5 to 1,500 gallons per minute. The most extensive and productive is the Spiritwood aquifer system. Chemical quality of the water varies greatly, but the dominant cations are sodium and calcium and the dominant anions are sulfate and bicarbonate. The Pierre aquifer consists of a fractured siliceous shale that ranges from 25 to 400 feet in thickness in the upper part of the Pierre Shale. The Pierre aquifer underlies all of Towner County. Wells developed in the aquifer generally yield less than 10 gallons per minute. The chemical quality of the water in the Pierre also is highly variable. The dominant cation is sodium and the dominant anion generally is chloride. The rural population and most communities in Towner County depend on ground water as a source of supply. (USGS)

2G. Water In Soils

NON-DARCIAN WATER FLOW IN PEAT,
Massachusetts Inst. of Tech., Cambridge. Dept. of Civil Engineering.
H. F. Hemond, and J. C. Goldman.
Journal of Ecology, Vol. 73, No. 2, p 579-584, July, 1985. 1 Fig, 14 Ref.

Descriptors: *Peat, *Permeability coefficient, *Seepage, Soil water, Flow discharge, Pore pressure, Darcys law, Interstitial water.

Dramatic changes in the apparent hydraulic conductivity of peat observed by several investigators during seepage-tube and auger hole tests in both recharge and depletion modes can be explained by the large elastic storativity of peat, which renders steady-state analytical methods inappropriate. Such observations alone are not inconsistent with Darcian peat behavior. A lesser degree of non-Darcian peat behavior suggested by constant head steady state experiments may be explainable in part by vertical effective stress and compressibility effects. Results of in situ conductivity tests in mires can also be affected by other factors, such as local alterations of vertical effective stress by the weight of observers. The three-dimensional, heterogeneous nature of the situation in the field further complicates analysis; for example, where large horizontal gradients are imposed on the peat by a seepage-tube test, local changes in peat-pore geometry due to changes of horizontal stresses may also occur. The accurate measurement and interpretation of peat hydraulic conductivity remains an extremely difficult problem. Darcy'a Law is seen to be appropriate for use in upper unhumified or slightly humified peats. Even in humified peats under natural conditions of constant pore-water chemistry, small hydraulic gradients, and fairly constant effective stress, the existing data may not be inconsistent with the satisfactory application of Darcy's Law. Field measurement methods which provide steady state condition and minimal alteration of effective stresses are likely to provide the most accurate information for hydrologic models. It is suggested that the minimum practicable alteration of pore pressure be a criterion for the design of methods to measure peat hydraulic conductivity under field conditions. (Baker-IVI)

CHARACTERIZATION OF PORE SIZE DISTRIBUTIONS WITHIN SOILS BY MERCURY INTRUSION AND WATER-RELEASE METHODS,
Illinois Univ. at Urbana-Champaign. Dept. of Agronomy.
K. R. Olson.
Soil Science, Vol. 139, No. 5, p 400-404, May, 1985. 1 Fig, 3 Tab, 12 Ref.

Descriptors: *Soil water, *Pore size, *Pores, *Pore water, *Mercury intrusion method, *Water release method, Roots, Sand, Clay, Soil properties.

Soil pore size distributions for undisturbed, oven-dried peds were measured and interpreted using mercury intrusion porosimetry. The pore size distributions were compared with those calculated from moisture release data. A correlation between water retention difference by water-release methods and water storage pore volumes (50 to 0.5 microns) by mercury intrusion was established with an R squared = 0.58 over a variety of soil texture and bulk density ranges. Most of the variation occurred for soil samples high in either sand or clay. In addition, root-restricting class limits were developed based on volume of root size pores (200 to 10 microns) within oven-dried peds that were large enough to permit root tip and root hair penetration. DESIGN OF A SENSITIVE AND PRACTICAL CLOSED-TOP INFILTROMETER,
Haryana Agricultural Univ., Hissar (India). Dept. of Soils.
R. S. Malik, S. K. Sharma, and J. S. Dhankar.
Soil Science, Vol. 139, No. 5, p 452-457, May, 1985. 1 Fig, 5 Tab, 14 Ref.

Descriptors: *Infiltrometers, *Infiltration, *Soil water, Soil types, Moisture meters, Measuring instruments, Water depth.

A two-piece, closed-top infiltrometer with a 10-cm diameter was designed which measures infiltration under constant and naturally occurring low surface water head. Field tests were conducted in cultivated sandy and fine loamy soils with varying ring size, depth, and surface water head conditions. Mean cumulative infiltrations obtained with this infiltrometer are not significantly different from those with an open-top, falling-head infiltrometer at all times. Measurements with the designed infiltrometer are more reproducible, and hence fewer infiltration runs are needed to characterize the average infiltration parameters of a given area. The mean and coefficient of variation in cumulative infiltration of 60 min are 13.88 and 8.29% in sandy soil, respectively. The corresponding values for an open-top, falling-head infiltrometer are 13.56 and 17.55%, respectively. The designed infiltrometer does not present parallax and floating material problems. The time lag in taking zero time reading is reduced from 6.3 to 2.4 s. The sensitivity of the designed infiltrometer is 0.025 cm; that of a conventional infiltrometer is 0.1 cm. It is more practical, in general, and for remote areas of short water supply, in particular. Mean cumulative infiltration did not differ significantly with increasing ring size from 10- to 30-cm diameter. The coefficient of variation decreased at all times with the increase in size. The optimum outer ring depth was 10 cm, which was equal to the inner ring depth. The cumulative infiltration increased with increase in surface water head at all times, especially when it is increased in the higher range from 5 to 10 cm. (Author's abstract)

ADIENT PERMEABILITY MEASURE-
N A TRIAXIAL SYSTEM,
l Survey, Denver, CO.
en, R. W. Nichols, and T. L. Rice.
ique, Vol. 35, No. 2, p 145-157, June
ig, 2 Tab, 20 Ref.

Descriptors: *Permeability, *Triaxial systems, *Flow-pump method, Soil properties, Soil types, Sand, Clay, Silt, Soil water, Unsaturated zone.

Permeability measurements were conducted with the flow-pump method on sand, sandy silt and silty clay specimens in a conventional triaxial system by introducing and withdrawing water at known constant flow rates into the base of a specimen with a flow-pump, and by monitoring the head difference induced across the length of the specimen with a sensititive differential pressure transducer. The results show that the previously reported advantages of the flow-pump method, compared with conventional constant head and falling head methods, were realized for permeability measurements in conventional triaxial equipment. These advantages are that direct flow rate measurements are avoided together with the associated errors that arise from the effects of contaminants on capillary menisci and the long periods of time involved in flow rate measurements; permeability measurements can be obtained much more rapidly and at substantially smaller gradients; errors from the small intercept in the otherwise linear flow rate versus hydraulic gradient relationship, and also from seepage-induced permeability changes, can easily be recognized and avoided or minimized. The results further show that the initial transient response of a specimen that precedes the steady state condition needed for a permeability measurement can require a substantial period of time. In this study the response times varied from a fraction of a minute for a sand specimen to more than 200 minutes for a silty clay specimen. Errors in permeability measurements from this transient response can easily be avoided with the flow-pump method but not with constant head and falling head methods. (Author's abstract)

DIFFERENTIAL EVAPO-TRANSPIRATION FROM A CLAY SURFACE AND ITS INFLUENCE ON EQUILIBRIUM POREWATER PRESSURE,
Golder Associates, Maidenhead (England).
R. E. Gibson, M. H. Goldsworthy, and A. M. Chandler.
Geotechnique, Vol. 35, No. 2, p 181-191, June, 1985. 5 Fig, 6 Tab, 7 Ref.

Descriptors: *Evapotranspiration, *Porewater pressure, *Clay, *Groundwater movement, Settlement, Soil water, Evaporation, Transpiration.

The derivation is presented of expressions resulting from a steady state groundwater flow approach to determining the porewater pressure changes caused by modification of the rate of evapo-transpiration over limited areas of the ground surface. Solutions to the expressions have been computed for positions throughout the soil layer for a variety of shapes and sizes of affected area. The tabulated results may be used to estimate the effects for a wide range of conditions by making use of the principle of superposition. Case histories are presented in which observations of porewater pressure changes and of ground movement are compared with the values derived from the tabulated results. (Author's abstract)

OBSERVATIONS OF THE BEHAVIOUR OF LARGE CORES OF SOIL DURING DRAINAGE, AND THE CALCULATION OF HYDRAULIC CONDUCTIVITY,
Oxford Univ. (England). Dept. of Agricultural and Forest Science.
W. R. Kneale.
Journal of Soil Science, Vol. 36, No. 2, p 163-171, June, 1985. 5 Fig, 2 Tab, 8 Ref.

Descriptors: *Permeability coefficient, *Drainage, *Soil water, Matric potential, Macropore channels, Interstitial water, Air entry.

This paper reports observations on the behavior of large cores of undisturbed clay-loam soil during the drainage of water under an imposed step in potential. Rates of outflow and the matric potential at various points in the core were recorded during drainage. The volumes of 'macropore-channels' (large, continuous voids) were estimated to be 0.005 cu m/cu m in a subsoil sample, and 0.026 cu m/cu m in a topsoil sample from arable land. The calculated values of hydraulic conductivity were found to vary with the size of the step in potential imposed on the sample at the start of each drainage experiment. The available evidence suggested that the apparant K/Psi m relationship was influenced by the rate that air could enter the soil to replace water during drainage. The degree of restriction on air movement was affected by the initial drainage behavior, and this varied with the imposed step in potential. (Author's abstract)

F. Baillon, J. Herbauts, and M. Tanghe.
Acta Ecologica, Vol. 6, No. 2, p 183-192, 1985. 3 Fig, 2 Tab, 21 Ref.

Descriptors: *Nitrogen, *Mineralization, *Hydromorphic soils, *Semois, *Belgium, Humic soils, Water table, Nitrification, Vegetation, Soil water.

In the alluvial plain of the Semois (Belgium), both in situ and in vitro, nitrogen availability of humic layers was studied in relation with the yearly fluctuations of the water-table in a sequence of more or less hydromorphic soils. The fluctuations of the water-table were measured using a sequence of 15 piezometers disposed throughout a transect overlying successively a peaty grassland with Molinia caerulea, a tall-herb community with Filipendula ulmaria and a reed-bed with Phalaris arundinacea. Results show that, during the vegetation period, nitrogen mineralization is almost not affected by the degree of hydromorphy of the humic layers: nitrogen mineralization rates are not significantly different in the 3 studied sites and in every case nitrification is the dominant process. ANALYSIS OF SOLUTE BREAKTHROUGH CURVES TO PREDICT WATER REDISTRIBUTION DURING UNSTEADY FLOW THROUGH UNDISTURBED STRUCTURED CLAY SOIL,
Oxford Univ. (England). Soil Science Lab.
R. E. White.
Journal of Hydrology, Vol. 79, No. 1/2, p 21-35, July, 1985. 4 Fig, 3 Tab, 29 Ref.

Descriptors: *Unsteady flow, *Clay, *Model studies, Solute transport, Soil water, Mixing, Diffusion, Interstitial water, Bypass flow, Structured soils.

Solutions of 5 or 10 mM CaCl2 were applied at constant rates of 7-14 mm/hr to the surface of large (23-cm dia. x 20-24 cm long) undisturbed cores of cracking clay soil. Cl- breakthrough was analyzed assuming a log-normal distribution of solute travel times. The resultant transfer function model (TFM) fitted the data well for moist or

prewetted cores (volumetric water content theta sub i from 0.35 to 0.49) but was inadequate for very dry cores (theta sub i approximately = 0.30) at the higher input rates. When extensive bypass flow occurred in the soil, the probability density function of solute travel times was not well represented by a log-normal distribution. The breakthrough data were also analyzed using a mixing model which postulated convective mixing of applied solution with resident soil water to form a mobile miscible volume, and diffusion of solute between the miscible and immiscible volumes of soil water. This model was used to predict the miscible volume and its change with time during unsteady flow through each core. The time-weighted average fractional miscible volume theta' sub m derived from the mixing model was in close agreement with theta sub m, calculated as the input water flux divided by the mean pore-water velocity given by the TFM. An essential feature of any model of solute transport in structured soils is the recognition of two domains of different flow characteristics which is some cases give rise to a log-normal distribution of pore-water velocities. SCALING THE EXPONENTIAL SOIL-WATER DIFFUSIVITY FOR SOILS FROM GHANA,
Ghana Univ., Legon. Dept. of Soil Science.
K. B. Laryea, and S. Abbenney-Mickson.
Journal of Hydrology, Vol. 79, No. 1/2, p 95-106, July, 1985. 4 Fig, 2 Tab, 8 Ref.

Descriptors: *Soil water, *Diffusivity, *Ghana, Infiltration, Mathematical equations, Soil type, Soil physical properties, Wetting.

Horizontal infiltration experiments were conducted on laboratory packed columns of six tropical soils chosen from two different ecological zones of Ghana (the coastal savannah and the forest regions). Calculated soil-water diffusivities of these soils were then fitted with an exponential regression equation to determine the values of the 'Universal' constants, alpha, gamma and beta. The scaling procedures suggested in the literature appear to be applicable to soils from Ghana. The constants alpha, beta and gamma vary according to the type of soil, sodium absorption ratio, and the scaling technique used to obtain the dimensionless soil-water diffusivity. Values obtained for alpha, gamma, and beta for these soils did not agree with those previously suggested, thus negating the proposed universality concept. The shape factor delta for the wetting profile appears to be around 0.90. (Moore-IVI)

INFLUENCE OF CYLINDRICAL MACROPORES ON STEADY-STATE INFILTRATION IN A SOIL UNDER PASTURE,
Sydney Univ. (Australia). Dept. of Soil Science.
K. R. J. Smettem, and N. Collis-George.
Journal of Hydrology, Vol. 79, No. 1/2, p 107-114, July, 1985. 2 Fig, 2 Tab, 17 Ref.

Descriptors: *Infiltration, *Macropores, *Pastures, Permeability coefficient, Infiltrometers, Steady-state infiltration.

Steady-state infiltration rates in a soil under native pasture were predicted from independent measurements of macropore volume fluxes and soil matrix hydraulic conductivity (K(sat)). K(sat) was measured by two methods which give slightly different results but were lower than areally averaged macropore fluxes. The predicted steady-state infiltration rates were compared with data obtained from cylinder infiltrometer measurements and agreement was excellent, indicating that steady-state infiltration was controlled primarily by the size and number of macropores within an infiltrometer ring. (Author's abstract)

PREDICTION OF STEADY-STATE PONDED INFILTRATION DISTRIBUTIONS IN A SOIL WITH VERTICAL MACROPORES,
Sydney Univ. (Australia). Dept. of Soil Science.
K. R. J. Smettem, and N. Collis-George.
Journal of Hydrology, Vol. 79, No. 1/2, p 115-122, July, 1985. 2 Fig, 3 Tab, 8 Ref.

Descriptors: *Infiltration, *Macropores, *Ponding, Simulation, Infiltrometers, Soil water, Permeability coefficient, Mathematical models, Soil properties.

A Monte Carlo simulation is used to predict the distributions of steady-state infiltration rate values for different infiltrometer ring sizes in a soil with vertical macropores. The simulation requires functional characterization of flow in soil macropores, coupled with a knowledge of macropore spatial dispersion. An additional option includes soil matrix hydraulic conductivity K(sat) which is assumed to be normally distributed with a known mean and standard deviation. The model was checked against measured data for two different ring sizes (0.071 and 0.0022 sq m) and good agreement was obtained. It is shown that in soil with vertical transmission macropores, the distribution of steady-state infiltration rate values becomes increasingly skewed as ring size is decreased, unless K(sat) is of sufficient magnitude to mask the macropore contribution. A method for determining the probability of a sensor with a known horizontal cross-sectional soil contact area intercepting at least one macropore is also presented. (Author's abstract)

LEACHING FRACTION BEYOND DEPTH X, CAUSED BY PERCOLATION OF A SOIL PROFILE WITH AN INITIAL SALT ACCMULATION AT ITS SURFACE,
Central Soil Salinity Research Inst., Karnal (India).
S. K. Gupta, D. Ramadurgaiah, and W. H. Van Der Molen.
Journal of Hydrology, Vol. 79, p 123-126, 1985. 1 Ref.

Descriptors: *Leaching, *Soil water, *Path of pollutants, *Percolation, Saline soils, Salts, Solute transport.

In many saline soils, large amounts of soluble substances are accumulated at the surface by capillary rise followed by evaporation. If such a soil is leached by rainfall or by application of irrigation water, these accumulated salts will move downward. By sampling the soil after a certain time, the concentration depth relation is obtained which can be used to find the parameters describing the leaching process. A characteristic for the progress made in leaching is the fraction of solute that moved beyond a certain depth x at the moment of sampling. An expression is derived for the leaching of a profile with a superficial accumulation of soluble substances. Use has been made of existing analytical solutions, now adapted to a Dirac delta function input of solute. With the concentration profile obtained, a formula follows for the fraction of solute leached beyond depth x at a given time t. (Baker-IVI)

Descriptors: *Suction lysimeters, *Lysimeters, *Monitoring, *Aeration zone, Vadose water, Land treatment, Waste disposal, Soil water.

Four questions relative to suction lysimeter performance have been raised by operators of land treatment systems. These questions deal with plugging of the porous segments of the lysimeters, soil suction operational ranges, adsorption onto and screening by the materials comprising the lysimeter parts, and loss of volatile organic negative pressures. The physical operatic lysimeter, the characteristics of the ly tested (high- and low-flow lysimeters with ceramic cups and lysimeters with porous (polytetrafluoroethylene) cups, and proced lowed in preparing them for testing are scribed and the results of experiments deali the first two questions - plugging and ope ranges - are discussed. The intake rate of lysimeters placed in the vadose zone, in mo of soils, will initially drop off rapidly, stabilize after about 15 liters of moisture ha drawn through the porous cups. Packing a line silica flour slurry around the cups o lysimeters negates most of the plugging as with finer particles in soils. The effective o range of ceramic lysimeters is between 0 centibars of suction independent of the use flour. The operating range of PTFE ly without silica flour is extremely narrow, the use of silica flour is extended to about bars of suction. The testing program indica all lysimeters should be checked for leal pressure techniques before field installat that lysimeters have 'dead' spaces, or reser from 34 to 80 mL of moisture that ca extracted from the cups, which must be ta account when determining moisture c rates. Information gathered in the test pr planned for inclusion in an EPA guidanc ment entitled 'Unsaturated Zone Monit Hazardous Waste Land Treatment Unit thor's abstract)

DISCRIMINATION OF SOIL PHYSICAL PARAMETERS, THERMAL INERTIA, AND SOIL MOISTURE FROM DIURNAL SURFACE TEMPERATURE FLUCTUATIONS,
Vrije Univ., Amsterdam (Netherlands). Inst. voor Aardwetenschappen.
A. A. van de Griend, P. J. Camillo, and R. J. Gurney.
Water Resources Research, Vol. 21, No. 7, p 997-1009, July, 1985. 12 Fig, 1 Tab, 41 Ref. NASA contract NAS5-23450.

Descriptors: *Soil physical properties, *Soil water, *Thermal inertia, *Soil temperature, Model studies, Remote sensing, Soil surface temperature, Heat flux, Transpiration.

A coupled heat and moisture flux model was used to study the influence of soil physical parameters and moisture content on diurnal surface temperature fluctuations. The study was performed for a grass cover under summer and autumn conditions for four soil types, ranging from sand to clay. The results show that it may be possible to use the daily maximum and minimum surface temperature measurements to discriminate several soil physical characteristics, including soil moisture. Further, ignoring the lower boundary heat flux, as is usually done in thermal inertia mapping but which can vary substantially in relation to different hydrological recharge and discharge areas, may lead to significant errors in the interpretation of soil moisture, thermal inertia, and transpiration. APPROXIMATE ANALYSIS OF THE BOREHOLE PERMEAMETER IN UNSATURATED SOIL,
Commonwealth Scientific and Industrial Research Organization, Canberra (Australia). Div. of Environmental Mechanics.
J. R. Philip.
Water Resources Research, Vol 21, No. 7, p 1025-1033, July, 1985. 10 Fig, 1 Tab, 21 Ref.

Descriptors: *Borehole permeameters, *Mathematical models, *Unsaturated flow, Permeameters, Unsaturated zone, Soil water, Permeability coefficient, Capillarity, Saturated zone.

An approximate analysis of the steady constant-head uncased borehole permeameter in homogeneous unsaturated soil is presented. A bulb-shaped region of saturated soil, the 'saturated bulb,' adjoins the water-filled length of the hole. The problem is solved by matching approximate models of the 'inner' saturated flow within the bulb and of the 'outer' flow in surrounding unsaturated soil. The quasilinear analysis, with sorptive number alpha characterizing the capillary properties of the soil, is applied to the outer saturated flow. Certain approximations made are geometrical, and other simplify the physics by treating gravity and capillarity as separable. The results agree well with the limited body of relevant detailed numerical solutions, and the model is consistent also with saturated flow results and formulae. In general, the capillary properties of the soil cannot be ignored: for a borehole of radius 0.05 m, the error committed in ignoring capillarity increases from 2.8 to 280% as alpha decreases from 10 to 0.1/m. The concepts and methods (the saturated bulb, use of the quasi-linear analysis, matching inner and outer flows) apply to a range of steady mixed saturated-unsaturated flow systems with water applied under positive hydrostatic pressure to an initially unsaturated soil mass. The study leads to some doubt about the practicality of using the borehole permeameter to measure saturated hydraulic conductivity in the absence of an independent determination of alpha. SUMMER SOIL MOISTURE CONTENT AND THE WATER TABLE IN A FORESTED WETLAND PEAT,
Toronto Univ. (Ontario). Dept. of Geography.
D. S. Munro.
Canadian Journal of Forest Research, Vol. 14, No. 3, p 331-335, June, 1984. 4 Fig, 2 Tab, 15 Ref.

Descriptors: *Soil water, *Water table, *Peat, *Wetlands, Beverly Swamp, Ontario, Soil moisture deficiency, Storage capacity, Swamps.

Soil samples were collected from the peat of the Beverly Swamp (Ontario), at weekly intervals, over three successive summers. The samples were analyzed to determine the distribution of soil moisture within the peat above the water table. A calculation scheme for the soil moisture deficit is defined and utilized to describe the behavior of the soil moisture regime over time. Linear regressions of soil moisture deficit against water table level are found to be statistically strong, but the slopes of the regressions change significantly from one summer to the next. Therefore, it is concluded that the position of the water table is not necessarily consistant indicator of storage capacity in wetlands. (Author's abstract)

EFFECT OF ENTRAPPED AIR ON WATER PERMEABILITY OF SOILS (THEORY AND EXPERIMENT),
Kiev State Univ. (USSR).
B. A. Faibishenko.
Water Resources, Vol. 11, No. 4, p 304-315, July-August, 1985. 5 Fig, 1 Tab, 10 Ref.

Descriptors: *Soil moisture, *Permeability coefficient, *Entrapped air, Unsaturated soils, Aeration, Water table, Model studies, Computers, Percolation.

The permeability of soils can be substantially affected by entrapped air, which remains in unsaturated soils of the zone of aeration and in quasi-saturated soils of the aquifer, reducing their permeability coefficient by 100 times and more. A model incorporating a system of equations should be used to predict water transport with consideration of entrapped air with a computer. For drainage conditions it is advisable to use in the zone of seasonal water table fluctuations in hydrogeological calculation the permeability coefficient and function K determined at the maximum possible volume of entrapped air for the investigated soils. Processes for moisture transport and percolation in the case of complete saturation and in a quasi-saturated state are described by one differential equation, the parameters of which vary for a different degree and character of soil saturation. During intake of water in monoliths under lab conditions and in rings and pits under field conditions the general character of variation of soil permeability with time is the same. Field methods can be used for determining the permeability coefficient of soils only with monitoring of the volume of entrapped air and spatial dynamics of water in soils. For practical purposes a combined approach can be recommended, which calls for: a field experiment - water intake tests in a pit for establishing the regularities of formation of the flow under natural conditions; a laboratory experiment - experiments on monoliths for determining the permeability coefficient as a function of the volume of entrapped air and hydrophysical properties of the soils and a computational experiment on a computer using a model for substantiating the necessary amount of field and lab works and for selecting and evaluating the correspondence of the mathematical model used to the natural process of percolation and moisture transport. ESTIMATION OF THE DEGREE OF DRAINAGE OF A TERRITORY,
Industrial and Scientific-Research Inst. for Engineering Surveys in Construction, Moscow (USSR).
V. V. Vedernikov, and E. S. Dzektser.
Water Resources, Vol. 11, No. 3, p 217-223, May-

June, 1984. 3 Fig, 12 Ref. Translated from Vodnye Resursy, No. 3, p 60-67, May-June, 1984.

Descriptors: *Drainage, *Mapping, *Hydrogeology, Groundwater, Hydrology, Mathematical equations, Geomorphology, Climate.

The degree of drainage of a territory is one of the most important complex hydrogeologic characteristics. The construction of hydrogeologic maps with zones of various degrees of drainage is widely used in reclamation engineering. An estimation of the degree of drainage of territories is important for planning cities, industrial complexes, routes of oil and gas pipelines or when developing areas for industrial and civil construction. The degree of drainage of a territory depends on a whole set of conditions: geomorphologic, hydrogeologic, geologic, and hydrologic-climatic. The proposed method, based on quantitative drainage criteria, broadens the limits of applicability of existing methods in view of the comparatively greater detail of the natural conditions of the investigated territories and possibilities for future use. COMPARISON OF THREE FIELD METHODS FOR MEASURING SATURATED HYDRAULIC CONDUCTIVITY,
Guelph Univ. (Ontario). Dept. of Land Resource Science.
D. M. Lee, W. D. Reynolds, D. E. Elrick, and B. E. Clothier.
Canadian Journal of Soil Science, Vol. 65, p 563-573, August, 1985. 2 Fig, 3 Tab, 21 Ref.

Descriptors: *Permeability coefficient, *Permeameters, Measuring instruments, Sand, Loam, Clay, Macropores, Air entrapment, Soil type, Statistical studies.

The saturated hydraulic conductivity, Ks, was measured on a loamy sand, a fine sandy loam, a silt loam and a clay at four 100-sq m-area sites in southern Ontario. Twenty measurements of Ks, were obtained by each of three different measurement techniques at each of the four sites. The techniques included: (1) the air-entry permeameter method; (2) the constant head well permeameter method using the Guelph Permeameter; and (3) the falling-head permeameter method applied to small soil cores. The Ks data were found to be better described by the log-normal frequency distribution than by the normal frequency distribution. Statistical comparison of the mean Ks values (Ks) indicated significant differences between some or all of the methods within each site. This site-method interaction was interpreted in terms of the influence of macropores and air entrapment on each of the measurement techniques. The measured Ks values ranged over an order of magnitude on the sand, one to two orders of magnitude on the loams, and three orders of magnitude on the clay. The Ks estimates averaged over the three methods were: 0.00003 m/s for the sand; 0.000002 m/s for the loams and 0.0000001 m/s for the clay. Although all techniques were able to discriminate between the three soil types, the best choice of method for any particular situation appears dependent on the required type and accuracy of the Ks measurement, soil type, and the various practical constraints on the investigation. POSSIBILITIES OF OBTAINING ZOOPLANKTON FROM THE RIVER PLONIA TO FEED YOUNG FISH,
Akademia Rolnicza w Szczecinie (Poland). Dept. of Hydrozoology.
B. Szlauer.
Acta Hydrobiologia, Vol. 25/26, No. 2, p 165-171, 1983/1984. 3 Tab, 12 Ref.

Descriptors: *Fish food, *Zooplankton, *River Plonia, *Poland, Fish, Aquaculture.

Little information is available on the occurrence of zooplankton at some distance from the outflows of rivers from lakes. A test method was proposed to elaborate on this problem which would allow the size of expected catches of zooplankton in a river to be estimated. Two sampling sites were chosen close to road bridges. Site I was 10 km from the outflow of the River Plonia from Lake Miedwie in a straight line. Site II was 18 km from this lake. The mean zooplankton flow at Sites I and II was respectively 74.86 and 57.88 kg wet weight per 24 hrs, ranging from 500 kg per 24 hr in May (Site I) to 0.32 kg/24 hr in August (Site II). During the period of demand for zooplankton, December to May, the zooplankton flow at Site I amounted to 23 310 kg. This was sufficient live food for the rearing of approximately 4000 kg of fry. The results of this study indicate it is possible to catch zooplankton in rivers flowing from lakes. This zooplankton may be caught even at a great distance from the lake, in those places most suitable from the point of view of their utilization. However, the catches may be abundant at such distant sites only in the period from November until May. (Baker-IVI)

The Plawniowice Duze Reservoir lies in the Forest Protective Belt in the Upper Silesia Industrial Region of Poland. It was constructed by flooding a sand pit heading with waters from the Toszecki stream, a tributary of the River Klodnica. Filling was completed in 1975. The area of the reservoir is about 285 ha, with a maximum depth of 16 m, and a mean depth of 11 m. The Plawniowice Duze reservoir is a lowland, extremely limnic dam reservoir. The lake hollow is characterized by the absence of asymmetry typical for dam reservoirs. A hydrobiological investigation was carried out in the reservoir, which demonstrated a dependence between the occurrence of pelagic rotifers and phytoplankton appearing in the water body. The rotifers occurred in greater numbers at the same depths as the phytoplankton. A dependence was also noted between the vertical distibution of rotifers and the water temperature and the amount of dissolved oxygen in the water. (Baker-IVI)

POPULATION DYNAMICS OF THE DEVILS HOLE PUPFISH,
Michigan Univ., Ann Arbor. School of Natural Resources.
B. Chernoff.
Environmental Biology of Fishes, Vol. 13, No. 2, p 139-147, 1985. 6 Fig, 1 Tab, 16 Ref.

Descriptors: *Population dynamics, *Devils Hole, *Nevada, *Pupfish, Model studies, Fish, Model studies, Mortality, Simulation, Water level, Seasonal variation.

A model is constructed to simulate fluctuations in monthly population sizes of the Devils Hole pupfish between January 1973 and August 1976. The strength of the proposed conceptual model is that is allows focusing on the relationship between population size and various biological and environmental factors. The model is shown to be capable of accurately predicting the population size over a 44 month period when several sources of mortality were included. The model was unable to project the long term effect of constant water-level management. The model should not be considered as an end in itself but rather as a valuable heuristic tool which can shed light on areas of needed research. A variety of biological parameters are estimated, and adult mortality is partitioned into natural and environmentally-dependent components. The simulations capture the seasonal fluctuations in population size, and only seven predicted population sizes differ from those observed by 20% or more. The model is used to make testable predictions about the life history of this species and interactions of the parameters are discussed. (Baker-IVI)

MIXED LAYER DYNAMICS IN A LAKE EXPOSED TO A SPATIALLY VARIABLE WIND FIELD,
Western Australia Univ., Nedlands. Dept. of Civil Engineering.
J. Imberger, and G. Parker.
Limnology and Oceanography, Vol. 30, No. 3, p 473-488, May, 1985. 17 Fig, 1 Tab, 18 Ref. Australian Water Resources Council project 80/119.

Descriptors: *Lakes, *Mixing, *Wind velocity, Lake circulation, Water circulation, Salinity, Density, Water temperature.

The formation of frontal structures in the surface mixed layer near the entrance of an embayment in a medium-sized lake were described with field measurements. The observed evolution of the fronts was interpreted in terms of three well defined dynamical regimes. The first, differential heating, is defined as the variable heat capture due to decreased surface heat losses and warmer surface water in the sheltered embayments. The second, variable deepening of the mixed layer, is induced by a sudden increase in wind speed in the open central areas of the lake, with only minimal mixing in the sheltered part of the lake. The third is the horizontal gravitational motion driven by the horizontal density gradients set up by the active deepening of the mixed layer in the exposed parts of the lake. Although detailed wind data were not available, observations of the temperature and salinity fields show the existence of fronts in lakes and strongly suggest the importance of the above mechanisms in determining the horizontal variability of these fields in the surface mixed layer of medium-sized lakes. PHOSPHORUS LIMITATION OF LOTIC PERIPHYTON GROWTH RATES: AN INTERSITE COMPARISON USING CONTINUOUS-FLOW TROUGHS (THOMAS RIVER SYSTEM, BRITISH COLUMBIA),
National Water Research Inst., Vancouver (British Columbia). Pacific and Yukon Region.
M. L. Bothwell.
Limnology and Oceanography, Vol. 30, No. 3, p 527-542, May, 1985. 3 Fig, 7 Tab, 72 Ref.

Descriptors: *Phosphorus, *Limiting nutrients, *Periphyton, *Thomas River System, *British Columbia, Nitrogen, Nutrients, Growth, Biomass, Algae, Chemical composition.

Periphyton growth rates and relative degrees of phosphorus deficiency were compared with onsite, continuous-flow troughs in three parts of the Thompson River system. Soluble reactive phosphorus (SRP) in the lower Thompson, North Thompson, and South Thompson Rivers averaged 3.4, 1.1, and 0.7 micro-g/liter. Several physiological and chemical composition parameters ranked the degree of P deficiency in the rivers in the same sequence as did SRP. Among these were alkaline phosphatase activity, V sub max for (P-32)O4(3-) uptake, and cellular N:organic P, Chl a:ATP, C:ATP, and C:organic P. Specific growth rates (mu) estimated by biomass accrual and by (C-14)O2 uptake usually, but not always, indicated higher mu with greater availability of P. However, relative specific growth rates (mu:mu sub max) consistently reflected the influence of P limitation. As assessed from N:organic P and by application of the Droop and Goldman-Carpenter equations, mu:mu sub max was 0.8-0.9 at the lower Thompson, 0.3-0.6 at the North Thompson, and 0.0-0.3 at the South Thompson sites. Hence, periphyton growth rates in the lower Thompson River were near the maximum set by temperature and light at ambient SRP of only 3-4 micro-g/liter. Evidence of P-limited growth rates in the South Thompson and North Thompson Rivers was found at temperatures approaching 0 C. (Author's abstract)

FACTORS CONTROLLING PHOSPHORUS LIMITATION IN STREAM SEDIMENTS,
State Univ. of New York Coll. at Cortland. Dept. of Biological Sciences.
R. L. Klotz.
Limnology and Oceanography, Vol. 30, No. 3, p

543-553, May, 1985. 5 Fig, 6 Tab, 30 Ref.

Descriptors: *Phosphorus, *Limiting nutrients, *Stream sediments, *Sediments, *New York, Microorganisms, Benthos, Alkaline phosphatase activity, Forest watersheds, Agricultural watersheds.

Factors influencing the phosphorus limitation of benthic microorganisms were determined for four streams (two agricultural and two forested) in central New York State over an annual cycle. Phosphorus limitation was measured biweekly as specific alkaline phosphatase activity (APA) of sediment samples. Analysis of variance showed the forested streams (sites 2 and 4) to have significantly different sediment APA from the agricultural streams (sites 1 and 3), the higher APA for the forested sites indicating greater phosphorus limitation. Stream total reactive phosphorus concentrations showed no relationship with watershed type, with mean annual values of 10.5 and 6.0 micro-g/liter for agricultural sites 1 and 3 and 4.1 and 9.6 for forested sites 2 and 4. With all sites grouped together, sediment APA had a low correlation with stream water phosphate ($r = 0.184$, $n = 73$). Phosphorus sorption isotherms showed sediments from agricultural streams to have higher phosphate sorption indices than forested sites and to sorb rapidly large amounts of phosphorus. This resulted in higher available phosphorus content for the agricultural sediments and lower sediment APA. (Author's abstract)

DISTRIBUTION AND CHARACTERISTICS OF CARBOXYPEPTIDASE ACTIVITY IN POND, RIVER, AND SEAWATERS, IN THE VICINITY OF TOKYO,
Tokyo Univ. (Japan). Dept. of Chemistry.
S. Hashimoto, K. Fujiwara, K. Fuwa, and T. Saino.
Limnology and Oceanography, Vol. 30, No. 3, p 631-645, May, 1985. 10 Fig, 4 Tab, 29 Ref. Ministry of Science, Culture and Education (Japan) grant-in-aid 58540349.

Descriptors: *Carboxypeptidase, *Ponds, *Rivers, *Seawater, *Tokyo Bay, *Japan, *Enzymes, Chlorophyll, Proteins, Water chemistry, Peptides, Organic carbon.

Enzymatic hydrolysis of the peptide bond between glycine and tryptophan was measured in river water, pond water, and seawater near Tokyo. Enzymatic activities were in the range between 0.1 and 3 mU/liter, 10-50% of the activity was due to cell-free (dissolved) enzymes (1 mU expresses the rate of hydrolyzing substrate at 1 nM/min at 25 C). According to gel permeation chromatography, the dissolved activity included several macromolecules with molecular weights between 30,000 and 500,000 daltons. The horizontal and vertical distributions of this activity were measured in Tokyo Bay and the open sea, where an appreciable amount was detected even at 1,400-m depth. Among various factors investigated (including pH, salinity, water, temperature, metal ions, and phosphorus concentrations), total organic carbon, particulate organic carbon, and especially chlorophyll a were positively correlated to the enzymatic activity in Tokyo Bay. The slope of regressions of chlorophyll a on carboxypeptidase activity for individual sampling points showed that the activity per unit of chlorophyll a increased when the sampling station was closer to the open sea. Although whole protein molecules are not decomposed in the dissolved state, small peptides may be degraded by the free dissolved enzymes. (Author's abstract)
W86-01418

ANNUAL LOSSES OF IRON FROM MOORLAND SOILS AND THEIR RELATION TO FREE IRON CONTENTS,
Stirling Univ. (Scotland). Dept. of Environmental Science.
I. C. Grieve.
Journal of Soil Science, Vol. 36, No. 2, p 307-312, June 1985. 1 Fig, 2 Tab, 14 Ref.

Descriptors: *Iron, *Moorland soils, *Soils, Chemical composition, Metals, Organic matter, Soil properties.

The temporal pattern of iron loss from a moorland catchment was investigated by intensive stream sampling. The field site was a 51 ha area of moorland in the Ochil Hills near Stirling, Scotland, drained by a small tributary of the Allan Water. Filtered water samples were used for the determination of dissolved iron by atomic absorption spectrophotometry and of dissolved organic matter by dichromate oxidation. Losses of iron from the catchment were calculated as the product of discharge and iron concentration, summed over time. The total loss in 1 year was 2.11 kg/ha of Fe, with a pronounced autumn maximum. Iron concentrations in stream water were strongly correlated with dissolved organic matter content, but again with seasonal variation. The autumn maximum for Fe losses relates to the flushing of DOM during autumn rewetting of the catchment. However, the DOM/Fe ratio indicates maximum iron transport per unit mass of DOM in the winter. Free iron content measured on a number of soils in the catchment ranged from 3.1 to 8.7 kg/sq m. Assuming soil development over 10,000 years, predicted loss of iron from the catchment is comparable in quantity to the amounts of free iron in soils. (Collier-IVI)

INTER- AND INTRA-HABITAT DISTRIBUTION OF LEECHES IN A EUTROPHIC ENGLISH LAKE,
Liverpool Univ. (England). Dept. of Zoology.
S. M. L. Randall, S. M. Spelling, and J. O. Young.
Archiv fur Hydrobiologie, Vol. 103, No. 4, p 419-444, June, 1985. 12 Fig, 9 Tab, 35 Ref.

Descriptors: *Leeches, *Ecological distribution, *Eutrophic lakes, *England, Habitats, Substrate, Reproduction, Biomass, Water depth, Migration.

In an eutrophic English lake, Erpobdella octoculata, Glossiphonia complanata and Helobdella stagnalis had their maximum abundance in waters of less than 1 m in depth. H. stagnalis was numerically dominant on stones, on plants and in detritus. E. octoculata had a greater relative abundance than G. complanata on plants and in detritus. For any one species, weight-structure and breeding activity were similar for populations living on stones and in beds of vegetation. Leeches showed no preference for stones of a particular size or texture. For each of the species, density and biomass were less but mean weight and the proportion of breeding animals were greater on stones than in the underlying subtratum. There was some evidence for a movement of leeches into the deeper littoral waters in the winter. (Author's abstract)

PHYTOPLANKTON PRIMARY PRODUCTION IN BRACKISH LAKE GREVELINGEN (SW NETHERLANDS) DURING 1976-1981,
Delta Inst. for Hydrobiological Research, Yerseke (Netherlands).
F. Vegter, and P. R. M. de Visscher.
Netherlands Journal of Sea Research, Vol. 18, No. 3/4, p 246-259, December, 1984. 3 Fig, 4 Tab, 33 Ref.

Descriptors: *Water resources development, *Flood control, *Environmental effects, *Phytoplankton, *Primary productivity, *Lake Grevelingen, *Netherlands, Carbon, Nutrients, Temperature effects, Water temperature, Light intensity, Chlorophyll.

Phytoplankton primary production in brackish Lake Grevelingen was studied from 1976 to 1981, inclusive, in connection with a number of environmental parameters. An evident tendency of increasing primary production from 1978 (90 g C/sq m/a) to 1981 (225 g C/sq m/a) has been shown, following a change in the hydrological regime of the lake in 1978, viz. the opening of a sluice between the lake and the North Sea. Especially increased nitrate concentrations may be responsible for the enhanced production. Primary production was triggered almost every year at the end of February with prevailing light conditions of 0.002-0.004 J/sq cm/s in the water column. Annual production data from Lake Grevelingen are comparable with literature values, measured in eutrophicated coastal areas. (Baker-IVI)

Descriptors: *Lake sediments, *Lake Grevelingen, *Netherlands, Environmental effects, Sedimentation, Sediment transport, Sediments, Particle size, Distribution.

Some basic sediment parameters from samples of 0 to 3 cm sediment depth were investigated at 430 stations in the recently formed Lake Grevelingen, to elucidate the history of sediment deposition in Lake Grevelingen and the former Grevelingen estuary. A geographical trend exists for the sediment median grain size, with increasing median grain size values towards the eastern part of the lake. This trend has been caused by sediment distribution processes under the former ebb and flood currents in the Grevelingen estuary. After enclosure of the estuary in 1971, much of the fine grained sediment material has been transported towards the deeper gullies. A reflection of this may be seen in the recent sediment maps for mud content and organic carbon content of the upper 0-3 cm sediment layer in Lake Grevelingen. (Baker-IVI)

SEDIMENT-WATER EXCHANGE IN LAKE GREVELINGEN UNDER DIFFERENT ENVIRONMENTAL CONDITIONS,
Delta Inst. for Hydrobiological Research, Yerseke (Netherlands).
P. Kelderman.
Netherlands Journal of Sea Research, Vol. 18, No. 3/4, p 286-311, December, 1984. 11 Fig, 3 Tab, 69 Ref.

Descriptors: *Lake sediments, *Lake Grevelingen, *Netherlands, Sediments, Nutrients, Water temperature, Phosphates, Turbulence, Silicates, Resuspension, Model studies.

The impact of various environmental factors on the phosphate and silicate sediment-water exchange in Lake Grevelingen has been investigated in a series of laboratory experiments under aerobic conditions. Silicate mobilization from the sediment showed a strong temperature dependence, with fluxes ranging from 5 mg Si/sq m/day at 5 C to 85 mg Si/sq m/day at 20 C. Phosphate mobilization fluxes ranged from 0.5 to 11 PO4-P/sq m/day at 5 and at 20 C respectively. The phosphate exchange fluxes showed a significantly linear negative correlation with the phosphate concentrations in the overlying water, in accordance with Fick's first law of diffusion. High P accumulation rates into the sediment were especially found at low water temperatures. Resuspension of the upper sediment layer was shown to enhance these P accumulation rates even more. Based on the results for four different sediment types, general relationships have been derived for the phosphate sediment water exchange as a function of water temperature and phosphate concentration in Lake Grevelingen. The results have successfully been applied in a simulation model for the phosphate concentration in Lake Grevelingen over the years 1974 through 1977. (Baker-IVI)

NUTRIENT CONCENTRATIONS IN THE INTERSTITIAL WATER OF LAKE GREVELINGEN SEDIMENT: EFFECTS OF SEDIMENT REDISTRIBUTION AND BENTHIC PRIMARY PRODUCTION PROCESSES,
Delta Inst. for Hydrobiological Research, Yerseke (Netherlands).
P. Kelderman.
Netherlands Journal of Sea Research, Vol. 18, No. 3/4, p 312-326, December, 1984. 7 Fig, 2 Tab, 75 Ref.

Descriptors: *Netherlands, *Lake Grevelingen, *Sediments, *Nutrients, *Interstitial water, Benthos, Primary productivity, Oxygen, Sedimentation, Ammonia, Nitrates, Phosphorus, Silicates, Water depth.

Interstitial water characteristics are a useful indicator for the various diagenetic processes in the sediment. Nutrient concentrations in the interstitial water were periodically investigated at 24 permanent stations in Lake Grevelingen, a recently enclosed estuary in the Netherlands. At the deeper stations (>7 m) in the lake, phosphate and silicate pore water concentration generally reach maximum values in the 0-3 cm sediment zone (typically 50 and 400 microgat/l respectively). These maxima are caused by the mineralization of reactive sediment material, that is continuously being redistributed towards the deeper areas in the lake. At the shallow stations (<7 m) local phosphate and silicate porewater maxima are often found in the top 0-1 or even 0-.5 cm layer. It is probable that mineralization of microphytobenthos cells plays a dominant role here. This implies that a light dependent nutrient depletion in the upper mm, or less, of the sediment must have occurred; an effect that could not be detected with the present interstitial water sampling technique, but has indirectly been shown to take place at a field station with high microphytobenthos primary production rates. Highly significant seasonal trends were found for the P, Si and NH4-N pore water concentration in the top layer at the deeper stations. Seasonal variations at the shallow station were virtually absent; light regime, and not temperature, may be the dominant factor here. (Baker-IVI)

CARBON FIXATION AND CHLOROPHYLL IN BOTTOM SEDIMENTS OF BRACKISH LAKE GREVELINGEN, THE NETHERLANDS,

Delta Inst. for Hydrobiological Research, Yerseke (Netherlands).
P. H. Nienhuis, and B. H. H. De Bree.
Netherlands Journal of Sea Research, Vol. 18, No. 3/4, p 337-359, December, 1984. 5 Fig, 6 Tab, 44 Ref.

Descriptors: *Lake Grevelingen, *Netherlands, *Lake sediments, *Carbon fixation, Chlorophyll, Bottom sediments, Pigments, Particulates, Organic carbon, Primary productivity, Benthos.

Chlorophyll a concentrations in the upper 10 cm (sliced per cm) of Lake Grevelingen (Netherlands) sediments are given for the years 1977-1980. Chlorophyll a in the upper cm of the bottom varied between 20-400 mg/sq m. Average values in 1-3 m deep sandy and silty-sandy stations amounted to 67.5-82.2 mg/sq m in the upper cm. A 7 m deep silty station contained on an average 42.7 mg/sq m chlorophyll a in the upper cm of the sediment. Both within year and year to year variations were large. A restricted number of phaeopigment data for 1977 revealed an average phaeopigment chlorophyll a ratio of 0.03 (sand) to 0.39 (silt). Particulate organic carbon (POC) measured in 1977 and 1978 in the top cm of the sediment showed annual average values ranging between 0.2 and 0.7% of sediment dry weight. C-14 fixation data in the light, as measured in a lab incubator, are given for 1979 and 1980, with highest values during summer and lower values in winter. Integrated annual values give average C-14 fixation estimates per station ranging between 47 and 71 g C/sq m/a, with a variation coefficient of 35 to 49% of the mean. Average C-14 dark fixation values varied between 13 and 27% of average light fixation values. An arbitrarily and tentatively derived net microphytobenthos primary production estimate for entire Lake Grevelingen amounts to 35 g C/sq m for 1979 and 32 g C/sq m for 1980. The relationship between POC and chlorophyll a concentration was sometimes significant; between annual chlorophyll a concentration and light fixation values it was not. The C-14 and the oxygen exchange methods both have serious drawbacks when applied to benthic systems. (Baker-IVI)

DYNAMICS, MIGRATION AND GROWTH OF NASSARIUS RETICULATUS (MOLLUSCA: PROSOBRANCHIA) COLONIZING SALINE LAKE GREVELINGEN (SW NETHERLANDS),
Delta Inst. for Hydrobiological Research, Yerseke (Netherlands).
R. H. D. Lambeck.
Netherlands Journal of Sea Research, Vol. 18, No. 3/4, p 395-417, December, 1984. 13 Fig, 3 Tab, 17 Ref.

Descriptors: *Lake Grevelingen, *Netherlands, *Snails, *Biomass, Growth rates, Population dynamics, Lakes, Migration.

The marine snail Nassarius reticulatus colonized Lake Grevelingen (Netherlands) after its creation in 1971. A population explosion took place in 1976. Dynamics, growth and biomass development were studied during 1976 and 1977. One generation a year was observed, with 1976 settlement around August 1. Densities at a 12 m deep station were mostly below 10/sq m, at two shallow (1 m) stations numbers increased to 40 to 60 sq m, as a result of immigration. Numbers at two 3 m stations, with peak values of 200 sq m, showed a cyclic pattern with a minimum in July 1977 due to migratory movements. Biomass increased over the period of investigation. The lowest maximum biomass was found at 12 m (0.16 g ADW/sq m) and the highest of 5.0 g at a 3 m station. In this survey the dominant 1976 year class showed a gradual decline from about 300 ind/sq m between 2 and 35 m to about 60/sq m in water deeper than 10 m. Growth rates were also depth dependent. Within the range of 2 to 25 m juveniles born in 1976 showed a maximum mean size of 6.8 mm after one growing season at 5 to 6 m depth against only 3.5 mm in deep water. Highest mean values after 2 growing seasons, vix. 16 mm, were reached at the 1 m deep stations, which figure might be inflated by size dependent immigration. Growth was poor (8 mm) at the 12 m station. Growth rates are similar to Swedish observations, but were reached at 10 to 50 times higher densities in Lake Grevelingen. (Baker-IVI)

Descriptors: *Lake Grevelingen, *Netherlands, *Population dynamics, *Nematodes, *Copepods, Crustaceans, Species diversity, Species composition, Biomass, Vertical distribution.

Data on density, diversity and species number of harpacticoids and nematodes from a 3 m deep station in Lake Grevelingen are reported over the period 1975-1980. Vertical distribution of both copepod and nematode densities are added. Over the 6 year period 95 species of nematodes and 26 species of harpacticoids have been identified. Neither diversity nor species number of harpacticoids changed significantly over the period. Nematode diversity and species number showed considerable changes, and especially the species composition evolved drastically over the years. The changes in feeding types among nematodes are discussed. Densities of both copepods and nematodes changed substantially over the 6 year period. Concurrent with a significant rise of the redox discontinuity layer from more than 20 cm sediment depth to less than 5 cm, the interstitial copepod fauna disappeared almost completely. The changes in vertical distribution of nematode densities were less pronounced though substantial. (Baker-IVI)

Descriptors: *Lake Grevelingen, *Netherlands, *Population dynamics, *Fish, Plaice, Flounder, Saline lakes, Growth, Fish food.

Within the scope of a carbon budget study in the 108 sq km saline Lake Grevelingen, investigations on the plaice and flounder populations were made during October 1979 to December 1981. Both populations were dominated by the 1979 year class that presumably entered the lake as larvae in the year the Brouwerssluice, which opens to the North Sea, was operative the whole year round. Due to high summer temperatures in the lake, juvenile plaice attained a mean length of 13.0 cm and a fresh weight of 27.4 g at the end of their first growing season. Total stock of plaice, excluding year class 1981, was estimated at an average of 1.3 million over 1980 and at 0.6 million fish over 1981. About 56% of the plaice food consisted of polychaetes, mainly consisting of in 1980 Arenicola marina (41%) and in 1981 A. marine (15%), Nereidae (15%) and Nephtys hombergii (11%). Total food consumption of the plaice population, excluding year class 1981, in 1980 and 1981 was estimated at 1.68 g and 1.41 g ash-free dry weight (ADW)/sq m/a. Annual consumption of O-group 1981 plaice was assessed at about 0.06 g ADW. The corresponding consumption of the flounder population was 1.14 g and 0.44 ADW, respectively. (Baker-IVI)

Lake Grevelingen is a former estuary
erlands which was isolated by enclosin
the influences of the rivers Rhine and M
1964 and from the influence of the Nort

e connection with the North Sea was
established in 1978. An annual gross
lance is presented for Lake Greveingen.
c primary production is the main source
material, with an estimated contribution
60%. From a comparison of the carbon
ith oxygen consumption measurements,
ncy of the planktonic auto- and microhe-
c community in producing particulate
aterial is estimated at 44%. This is a high
pared to efficiencies of deeper coastal
he western English Channel and off the
ast (2.34%). The pelagic and benthic
nt of the lake are tightly coupled by the
tivity of benthic macrofauna, causing a
g pressure on phytoplankton (estimated
f net production) and a transport of
organic particles to the sediment by
of feces and pseudofeces, exceeding pas-
with a factor 3 to 4. In agreement with
n the western Wadden Sea, the role of
small foodweb in consuming primary
tter is probably limited. (Baker-IVI)

River, Fish management, Fish pop-
ations, Model studies.

The population dynamics of natural and hatchery coho salmon (Oncorhynchus kisutch) were estimated for three regions, (1) Washington coastal, (2) Columbia River region, and (3) Oregon/California coastal, using pooled time-series and cross-sectional data. Two functional forms were compacted: the Beverton-Holt and Ricker models. Both models yielded very similar results. In both cases, we found that the natural coho stock recruitment is significantly affected by parent stock level (positive), parent stock density (negative), river flow (positive), and hatchery smolt release (negative). The significant factors affecting hatchery coho salmon were smolt release level (positive), smolt release density (negative), and upwelling (positive). (Author's abstract)

WATER CIRCULATION IN SMALL ARCTIC LAKES IN WINTER,
Department of Fisheries and Oceans, Winnipeg (Manitoba). Freshwater Inst.
H. E. Welch, and M. A. Bergmann.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 42, No. 3, p 506-520, March, 1985. 13 Fig, 12 Ref.

Descriptors: *Water circulation, *Arctic zone, *Lakes, *Winter, *Saqvaqjuac, *Northwest Territories, Mixing, Salinity, Stratification, Seasonal variation, Thermodynamics.

Dye experiments and detailed measurements of conductance and temperature in small lakes at Saqvaqjuac (63 degrees 39' N, 90 degrees 39' W, Northwest Territories) showed how water circulated in midwater. Stored heat returning from the sediments warms adjacent water, which then sinks downslope. Water immediately beneath the ice moves laterally shoreward, picking up cryoconcentrated salts and sinking downslope. Displacement of deep waters upward at the lake center is postulated as completing the circulation. Rates of water movement are on the order of 10 m/d in 2- to 10-ha lakes. This type of winter circulation is expected to be ubiquitous throughout the arctic. (Author's abstract)

WINTER RESPIRATION OF LAKES AT SAQVAQJUAC, N.W.T.,
Department of Fisheries and Oceans, Winnipeg (Manitoba). Freshwater Inst.
H. E. Welch, and M. A. Bergman.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 42, No. 3, p 521-528, March, 1985. 4 Fig, 3 Tab, 20 Ref.

Descriptors: *Northwest Territories, *Saqvaqjuac, *Lakes, *Respiration, *Winter, Arctic zone, Plankton, Carbon radioisotopes, Methane, Water pollution effects.

Winter oxygen consumption rates at 64 degrees N latitude were measured for 11 lake years. They ranged from 0.131 to 0.306 g O2/sq m/d. They were not correlated with lake depth, in contrast with the winter respiration rates of temperate lakes. We suggest that this difference results from lower summer temperatures and a lower proportion of planktonic respiration in arctic as compared with temperate lakes. C-14 estimates of annual photosynthesis were generally lower than estimated annual respiration, and the C-14-measured photosynthesis beneath the ice in winter was generally too low to account for the actual amounts of oxygen evolved by photosynthesis. In one lake a 50% increase in annual production resulted in an increase of only 19% in winter respiration, suggesting that lake respiration is an integrative process that averages out production over a period of years. Addition of methane gas to simulate a gas pipeline break to a lake resulted in an immediate 67% increase in lake respiration rate. (Author's abstract)

WATER TEMPERATURE AS THE PRIMARY INFLUENCE ON TIMING OF SEAWARD MIGRATIONS OF ATLANTIC SALMON (SALMO SALAR) SMOLTS,
Direktoratet for Vilt og Ferskvannsfisk, Sandnes (Norway). Forskningsstasjion for Ferskvannsfisk.
B. Jonsson, and J. Ruud-Hansen.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 42, No. 3, p 593-595, March, 1985. 1 Fig, 1 Tab, 18 Ref.

Descriptors: *Water temperature, *Salmon, *Fish migration, *Norway, *Imsa River, *Smolts, Lunar cycle, Water flow, Rivers, Migration, Animal behavior.

Using multiple regression models the correlation of water temperature, water flow, cloudiness, and lunar cycle with the timing of the yearly descent of Atlantic salmon (Salmo salar) smolts in the Norwegian Imsa River, 1976-83 was tested. Water temperature between 9 April and 16 May explained 91, 95, and 89% of the yearly variation in date of 25, 50, and 75% cumulative smolt descent, respectively. The regression models were not very sensitive to variations of which date recording of the temperature was started and stopped. The start of the yearly smolt run was not triggered by a specific water temperature or a specific number of degree-days, but was controlled by a combination of temperature increase and temperature level in the river during spring. There was no significant correlation between smolt descent and any of the other environmental variables tested. (Author's abstract)

METHOD FOR MEASURING HORIZONTAL TRANSPORT OF ORGANIC CARBON OVER SEDIMENTS,
Dalhousie Univ., Halifax (Nova Scotia). Dept. of Oceanography.
J. Grant.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 42, No. 3, p 595-602, March, 1985. 3 Fig, 24 Ref.

Descriptors: *Organic carbon, *Sediments, *Nutrient transport, Sand, Beaches, Benthos, Deposition.

Prewashed, precombusted sand from a sheltered beach in Nova Scotia was returned to the beach at low tide in metal pans. Hourly sampling of pans during high tide was used to assess gross deposition of organic carbon to the bed, with sampling at successive low tides to derive net deposition rate. Resuspension was considered to be the difference between gross and net deposition. Short-term burial of carbon was measured by vertically sectioning pan samples. The results indicate that due to resuspension, the rate of net deposition over 2d (11 g C/sq m/h) was only 42% of the rate of gross deposition that occurred during a single high tide. The method is useful because it can resolve the short-term particle fluxes that may be trophically important to benthic communities. (Author's abstract)

SURVEY OF THE FRESHWATER MUSSEL FAUNA OF THE KANAWHA RIVER SEPTEMBER 1981-SEPTEMBER 1982,
West Virginia Dept. of Natural Resources, Charleston. Div. of Water Resources.
J. E. Schmidt, and M. A. Zeto.
Proceedings of the West Virginia Academy of Sciences, Vol. 55, No. 2/3/4, p 72-75, 1983. 1 Fig, 1 Tab, 5 Ref.

Descriptors: *Mussels, *Kanawha River, *West Virginia, Species composition, Aquatic population, Rivers, Benthos.

Freshwater mussels (naiads) were collected from the Kanawha River, West Virginia, at several locations between Winfield and Falls View as part of a statewide survey to identify naiad populations.

Sampling took place during the Fall of 1981 and the Fall of 1982 when the river was low and clear. Naiad populations were sampled with a 10-foot dovetail mussel brail and sight/hand collecting. Nineteen species of naiads and the asiatic clam Corbicula sp. were collected. The majority (18 species) were collected in the seven-mile stretch of the Kanawha River downstream of Kanawha Falls. Two species - Cyprogenia stegaria and Obliquaria reflexa are very rare in West Virginia. Only Corbicula sp. and one naiad species, Anodonta g. grandis, were collected downstream of Charleston. No endangered species were collected, although a population of Lampsilis abrupta (= orbiculata) is known to occur downstream of Kanawha Falls near Deepwater. (Author's abstract)

AQUATIC VEGETATION OF A NATURAL MARL LAKE IN WEST VIRGINIA,
West Virginia Univ., Morgantown. Dept. of Anatomy.
R. Bartgis.
Proceedings of the West Virginia Academy of Science, Vol. 55, No. 2/3/4, p 92-101, 1983. 2 Fig, 2 Tab, 24 Ref.

Descriptors: *Aquatic vegetation, *Marl lakes, *West Virginia, *Lake Louise, *Jefferson County, Mosses, Pondweed, Elodea, Duckweed, Species composition.

Lake Louise is a 14.5 m deep natural marl lake in Jefferson County, West Virginia. The aquatic vegetation of the lake occurs primarily in four concentric zones associated with increasing water depth. Each zone is characterized by a distinct plant community. In July 1982 the percent cover of each vascular and bryophytic species was recorded for each community. Dominant macrophytic species in these communities included the emergents Sparganium eurycarpum, and Nasturtium officinale and Veronica anagallis-aquatica in the two shallowest zones, respectively; Potamogeton spp. in an intermediate zone; and Elodea canadensis in the deepest zone. In addition, a fifth separate community dominated by Potamogeton crispus has developed in a small cove of the Lake. Within a community, vertical stratification also occurred. For example, the floating thalloid Lemna minor often formed a prominent surface layer. The flora of Lake Louise is similar to that of marl lakes in the glaciated northeastern United States. Community structure, such as species richness and number of dominants, was generally less complex at Lake Louise than in the northern lakes. (Author's abstract)

LIFE HISTORY AND ECOLOGY OF THE ALDERFLY, SIALIS AEQUALIS BANKS, FROM FLATFOOT CREEK, MASON COUNTY, WEST VIRGINIA,
West Virginia Dept. of Natural Resources, Charleston.
R. W. Gatewod, and D. C. Tarter.
Proceedings of the West Virginia Academy of Science, Vol. 55, No. 2/3/4, p 102-113, 1983. 3 Fig, 3 Tab, 18 Ref.

Descriptors: *Flatfoot Creek, *Mason County, *West Virginia, *Alderflies, *Ecology, Hydrogen ion concentration, Water quality, Larvae, Growth stages.

The alderfly Sialis aequalis Banks, from Flatfoot Creek, Mason County, West Virginia, was studied relative to its life history and ecology between April 1978 and May 1979, and its low pH tolerance experimentally estimated in the laboratory. Larvae were collected along the stream margins from a substrate of vegetative debris, mud, and silt. Larvae were detritivorous in their feeding habits, despite the high food potential of their habitat. Their diet was infrequently supplemented with chironomids and other dipterans. Length frequency distributions for larvae indicated one size class for the population, and thus a univoltine life cycle. Growth rate, based upon mean head capsule width, was optimal during the first month of the larval stage (May-June). No increase in head capsule width was observed in February and March, the final months of the larval stage. Pupation in the laboratory was variable in duration, ranging from 10 to 22 days. In the field, pupation began in late March and concluded 4 to 5 weeks later. Adults were first observed in late April, and none were sighted after May 10. Ovarian eggs of adult females ranged in number from 402 to 818, -x = 657. Mean egg length and width were 0.23 and 0.61 mm, respectively. The 96-hour median tolerance limit for low pH for S. aequalis larvae was 2.3. W86-01595

Illinois Natural History Survey, Champaign.
R. W. Larimore, and D. D. Garrels.
Fisheries, Vol. 10, No. 2, p 10-16, March/April, 1985. 8 Fig, 2 Tab, 10 Ref.

Descriptors: *Aquatic habitats, *Fish populations, *Streams, Habitats, Monitoring, Radiotelemetry, Animal behavior, Ecology, Fish behavior.

Five methods were developed for locating and identifying an undisturbed, free-swimming, stream fish. These methods used (1) color-coded tags, (2) fixed electrodes, (3) optical measurements, (4) night collections, and (5) radiotelemetry. They permitted observations of most kinds of fishes, at any time of day or night, during any season (including under ice), and from streams of different sizes. Although no one method was equally useful in all situations, the methods were evaluated according to their effectiveness in determining habitat preferences of different fish species under various stream conditions. The importance of precision in locating a fish and its habitat was emphasized by the finding of significant differences in physical measurements over extremely small areas. (Author's abstract)

SIMULTANEOUS IN-STREAM NITROGEN AND D.O. BALANCING,
Texas Univ. at Dallas, Richardson. Callier Center for Communication Disorders.
J. J. Warwick, and A. J. McDonnell.
Journal of Environmental Engineering, Vol. 111, No. 4, p 401-416, August, 1985. 3 Fig, 4 Tab, 39 Ref.

Descriptors: *Nitrogen, *Dissolved oxygen, *Water analysis, *Model studies, Nutrients, Water quality, Ammonia, Nitrates, Nitrites.

A one-dimensional, pseudo unsteady state, water quality model (Simultaneous Nitrogen and Oxygen Analysis Program - SNOAP) was developed to simultaneously solve both nitrogen and dissolved oxygen mass balance equations. Expressions are derived to estimate ammonia-N exsolution, bacterial ammonia-N uptake, and aquatic plant ammonia-N assimilation in terms of standard water quality indices. The SNOAP model calculates hourly values for all nitrogen species reaction rates (including nitrification and denitrification) based on observed in-stream variation of organic-N, ammonia-N, nitrite-N, nitrate-N, dissolved oxygen, temperature, and pH. An iterative solution algorithm is required to simultaneously solve the nitrogen and dissolved oxygen mass balance equations. This iterative approach is stable and results in relatively quick convergence. Erroneous values of observed nitrogen species or dissolved oxygen variation, or both, may result in an impossible situation for simultaneous nitrogen and dissolved oxygen mass balance solution. This nonconvergence feature is a significant attribute, in that is allows for a systematic screening of measured water quality data. (Author's abstract)

NITROGEN ACCOUNTABILITY FOR FERTILE STREAMS,
Texas Univ. at Dallas, Richardson. Callier Center for Communication Disorders.
J. J. Warwick, and A. J. McDonnell.
Journal of Environmental Engineering, Vol. 111, No. 4, p 417-430, August, 1985. 6 Fig, 7 Tab, 12 Ref.

Descriptors: *Nitrogen, *Streams, *Dissolved oxygen, *Water quality, *Model studies, Denitrification, Ammonia, Water pollution effects, Wastewater.

The Stream Nitrogen and Oxygen Analysis Program (SNOAP) is a one-dimensional, pseudo unsteady state, water quality model, which simultaneously solves both nitrogen and dissolved oxygen mass balance equations. The SNOAP model was successfully calibrated and verified for three, independent, data intensive water quality surveys. The modeled stream system was unsteady due to significant upstream impact from wastewater treatment plant effluent discharges. Denitrification was found to be the dominant total nitrogen sink. Average denitrification rates calculated by the SNOAP model range from 22.0-43.6 mg-N/sq m/hr. The computed values compared quite favorably with measured laboratory sediment denitrification rates which ranged from 28.2-39.2 mg-N/sq m/hr. In addition, the rate of ammonia-N decay was found to be the most accurate nitrogen species estimator of in-stream nitrification rates. (Author's abstract)

TRITIUM IN NATURAL WATERS OF MOLDAVIA AND A HYDROGEOLOGICAL INTERPRETATION OF THE RESULTS OF ITS DETERMINATION,
Akademiya Nauk Moldavskoi SSR, Kishinev. Inst. of Geophysics and Geology.
I. V. Zelenin, I. E. Verbitskii, I. K. Morkovkina, and V. V. Romanov.
Water Resources, Vol. 11, No. 1, p 324-334, July-August, 1984. 3 Fig, 4 Tab, 17 Ref. Translated from Vodnye Resursy, No. 4, p 70-81, July-August, 1984.

Descriptors: *Tritium, *Natural waters, *Moldavia, *Dnestr River, *Prut River, *USSR, River water, Precipitation, Groundwater, Water analysis, Groundwater movement, Aquifers.

The main hydrographic elements of Moldavia (USSR) are the Dnestr and Prut rivers. They originate in the Carpathians and have mean annual discharges respectively of 293 and 74 cu m/sec. The main aquifer complex is represented mainly by limestones of Baden-Sarmatina age. Its thickness reaches 100-150 m. The character of groundwater movement is quite complex due to the variability of the conditions of their recharge and discharge, inhomogeneity of the seepage properties of the rocks, intense water withdrawal from wells, and also by the absence in the geological section of thick, persistant impervious horizons which could serve as regional aquicludes. The groundwaters in the cover deposits of divides are partially directed toward the thalwegs of the erosional incisions, where they merge with the waters of the floodplain alluvium, and partially percolate into lower lying aquifers. In 1978-80 the tritium concentrations in river waters varied mainly from 40 to 90 TU. Neither regional nor temporal trends were noted in this case. The observed variations, in particular, are related to the nonuniformity of tritium concentrations in precipitation. Especially noticeable is the relation between tritium concentrations in river water and precipitation for the Dnestr River, where the effect of regulation of surface runoff is apparently not felt so strongly as in small rivers. In the overwhelming majority of cases the tritium concentrations in rivers are less than in precipitation, by about 30% on average in small rivers. This indicates a considerable role of the groundwater component in feeding rivers and agrees well with the hydrological estimate of the portion of groundwaters (23-27%) in the river runoff of the Dnestr-Prut interfluve. INVESTIGATION OF CO2 GAS EXCHANGE IN A CONVECTIVELY MIXED LAYER,
Moscow State Univ. (USSR).
A. O. Kokorin.
Water Resources, Vol. 11, No. 4, p 343-347, July-August, 1984. 1 Fig, 11 Ref. Translated from Vodnye Resursy, No. 4, p 90-94, July-August, 1984.

Descriptors: *Carbon dioxide, *Convection, *Gas exchange, Temperature effects, Stratification, Model studies, Oxygen transport, Mixing.

The conditions of fall-winter cooling accompanied by convective mixing of the upper layer of the water body and gradual deepening of the boundary of the convectively mixed layer are examined. The experimental profiles obtained made it possible to calculate the flow of carbon dioxide from water into the air and the average gas exchange rate k. The flow and gas exchange rate were calculated for 10 experimental series, each of which consisted of a period of heating of the basin from above (2-4 days) and period of cooling accompanied by convective mixing (6-9 hr). The CO2 distribution with respect to depth is determined by processes of diffusion and gas exchange across the interface and also by the chemical equilibrium between various carbonate forms. The concentration gradients of various carbonate forms are not equal among

themselves and therefore independent diffusion can lead to a redistribution of the total concentration of inorganic carbon between carbonate forms. A model is proposed which proved able to satisfactorily describe the experimental data. The formula used in the model for calculating the exchange coefficient during convective mixing gave values of the coefficient close to those found in natural water bodies, and it is assumed that the given calculation scheme will work satisfactorily also in the case of gas transport during fall-winter cooling of the ocean. In a simplified form the model was tested for calculation of oxygen transport. (Baker-IVI)

HYDROLOGICAL AND HYDROCHEMICAL ASPECTS OF THE TRANSFORMATION OF ORGANIC MATTER IN THE MOZHAISK RESERVOIR,
Moscow State Univ. (USSR).
L. B. Berdavtseva, and G. V. Tsytsarin.
Water Resources, Vol. 11, No. 4, p 370-377, July-August, 1984. 4 Fig, 3 Tab, 12 Ref. Translated from Vodnye Resursy, No. 4, p 121-129, July-August, 1984.

Descriptors: *Organic matter, *Mozhaisk Reservoir, *Hydrology, Chemical analysis, Phosphorus, Dissolved oxygen.

An analysis of the transformation of organic matter in the Mozhaisk reservoir on the basis of the indices of color, permanganate oxidizability (PO), and dichromate oxidizability (DO) in the annual cycle showed the main cause of the most considerable changes in the relationship between the investigated indices is occurrence of labile organic matter (LOM) related to intensification of production-destruction processes. All changes in the relationships between the investigated indices occur synchronously. The character of the relation between color, PO and DO changes practically simultaneously in response to an increase of the amount of LOM in the reservoir, which makes it possible to estimate the direction of processes forming the water quality at each given moment on the basis of one of the relationships or both simultaneously. Two extreme types of dependence, expressed by the equation of linear regression between the investigated indices, which conditionally characterize the maximum degree of transformation and maximum degree of instability of OM were distinguished. SPACE-TIME INHOMOGENEITY OF DISTRIBUTION OF ORGANIC MATTER IN THE MOZHAISK RESERVOIR,
Moscow State Univ. (USSR).
M. G. Ershova, M. B. Zaslavskaya, and N. M. Zyablova.
Water Resources, Vol. 11, No. 4, p 378-385, July-August, 1984. 4 Fig, 7 Tab, 12 Ref. Translated from Vodnye Resursy, No. 4, p 130-138, July-August, 1984.

Descriptors: *Mozhaisk Reservoir, *USSR, *Organic matter, Reservoirs, Chemical composition, Seasonal variation, Temporal distribution.

Within an accuracy of 25%, the study showed the effect of production-destruction processes on the average organic matter concentrations in individual sufficiently large stretches and in the entire volume of the Mozhaisk reservoir (USSR) is insignificant and it can be neglected in such calculations. It is possible that this conclusion is applicable also to other more eutrophic reservoirs of the forest zone with seasonal streamflow regulation. The characteristic weather changes for this zone during the growing season result in the times of dominance of the production of organic matter are replaced by times of dominance of destruction of autochthonous organic matter and on the whole the average concentration of organic matter is to a considerable extent determined by the amount of allochthonous matter introduced from the drainage basin. (Baker-IVI)

FORMATION OF THE HYDROBIOLOGICAL AND HYDROCHEMICAL REGIME OF THE NORTHERN DONETS-DONBAS CANAL (1958-1981),
Central Water Monitoring, Research, Planning, and Surveying Lab. (USSR).
A. I. Kovrizhnykh.
Water Resources, Vol. 11, No. 4, p 391-396, July-August, 1984. 2 Ref. Translated from Vodnye Resurnye, No. 4, p 144-150, July-August, 1984.

Descriptors: *Northern Donets-Donbas Canal, *USSR, *Bottom sediments, Canals, Erosion, Siltation, Phytoplankton, Velocity, Transparency, Bottom sediments.

The Northern Donets-Donbas Canal (USSR) has been operating for more than 20 years. During this period, the main characteristics of the hydrobiological and hydrochemical regimes of the canal at different stages of its operation have been established. Substantial changes were noted in the hydrobiological regime of the canal. Impoverishment of the species composition of phytoplankton occurred due to the elimination of green algae and the abundance of blue-greens decreased. In the phytobenthos the quantity of green filmentous algae decreased considerably and the mass development of Vaucheria and appearance of Thorea occurred. The abundance of submersed higher aquatic plants decreased and a tendency toward an expansion of the areas occupied by amphiphytes was noted. Among the main interdependent factors that caused these changes are an increase of flow velocities, decrease of water transparency, siltation, and erosion and redistribution of bottom sediments in the canal. Water Resources, Vol. 11, No. 4, p 396-401, July-August, 1984. 1 Tab, 29 Ref. Translated from Vodnye Resursy, No. 4, July-August, 1984.

Descriptors: *Dvina Basin, *USSR, *Biomass, *Helminths, *Fish parasites, Runoff, Seasonal variations, Shallow water, Lake Kubenskoe, Lake Lacha, Lake Vozhe, Parasites, Hydrological regime.

The region of Lakes Kubenskoe, Lacha, and Vozhe belongs to the excess moisture zone of the European sector of the USSR. Lake Kubenskoe is a large shallow water body with an area of 400 sq km, average depth of 2.5 m, and maximum depth of 4.5 m. The variation of individual elements of the climate is governed by the effect of certain types of atmospheric circulation. The annual distribution of the runoff of the rivers, creeks, and brooks emptying into Lake Kubenskoe mainly determines its level regime. All three lakes are intensely overgrown by macrophytes. In the winter the dissolved oxygen content in the water does not exceed 32% of saturation. During inflow of Sukhona waters into Lake Kubensoe an overall increase of biogenic substances in it is possible. Many fish parasites have favorable ecological conditions in the lake for development. Some reservoirs constructed on rivers possess their own hydrobiocenose, including invertebrates and fishes. Beds of macrophytes with an invertebrate fauna characteristic for them will appear in the littoral, well-heated stretches with a weak current. With time they will become the nesting sites of fish-eating birds, which will lead to increased infestation of fishes by cestodes and trematodes. The available ichthyoparasitologic data sho number of helminths having epizootol epidemiological significance are found fishes of Lake Kubenskoe and the Sukh (Baker-IVI)

R. W. Howarth, and J. J. Cole.
Science, Vol. 229, No. 4714, p 653-655, August, 1985. 1 Fig, 1 Tab, 38 Ref. NSF grants BSR-83-05176 and INT-83-04275.

Descriptors: *Limiting nutrients, *Molybdenum, *Phytoplankton, *Nitrogen, Marine environments, Coastal waters, Lakes, Algal growth, Sulfates, Phosphorus, Nitrogen fixation, Nitrates.

In most lakes, the supply of phosphorus controls primary productivity, yet phytoplankton productivity in most estuaries and coastal seas is controlled by nitrogen supply. Rates of nitrogen fixation may be low in coastal waters because molybdenum availability is low. In a series of experiments examining the uptake of radioactive Mo-99 by phytoplankton, environmentally realistic concentrations of sulfate inhibit molybdate assimilation. Sulfate inhibition of molybdate assimilation by phytoplankton makes molybdate less available in seawater than it is in freshwater. As a result, nitrogen fixation and nitrate assimilation, both processes that require molybdenum, may require a greater expenditure of energy in seawater than in freshwater. Experimentally increasing the ratio of sulfate to molybdate inhibits molybdate uptake, slows nitrogen fixation rates, and slows the growth of organisms that use nitrate as their nitrogen source. Descriptors: *Lake Champlain, *Mussels, *Distribution, Fall line, Migration, Species composition, History.

Lake Champlain occupies a large shallow basin in northeastern North America and drains to the St. Lawrence River. The freshwater mussel fauna of the lake's drainage system includes both Northern Atlantic and Interior Basin species. An analysis of the distribution of the mussel species in the eastern and southern drainage streams of Lake Champlain reveals that fall lines have controlled upstream migration at various stages during the lake's postglacial history. Species composition differs above and below fall lines within drainage streams and varies geographically between drainage streams. Such distribution patterns may be explained by proposed periodic invasions of Lake Champlain by species during specific postglacial lake stages. (Author's abstract)

EFFECTS ON THE FOREST FLOOR OF WHOLE-TREE HARVESTING IN AN APPALACHIAN OAK FOREST,
Virginia Polytechnic Inst. and State Univ., Blacksburg. Dept. of Forestry.
J. E. Johnson, D. W. Smith, and J. A. Burger.
American Midland Naturalist, Vol. 114, No. 1, p 51-61, July, 1985. 2 Fig, 4 Tab, 40 Ref.

Descriptors: *Whole-tree harvesting, *Logging, *Oak trees, *Nutrients, Forest management, Soil solution, Clear-cutting, Soil temperature, Ammonia, Nitrates, Potassium, Soil water, Cycling nutrients.

The size of the forest floor nutrient pool and degree of mineralization from this pool (as measured by nutrient concentrations in the soil solution) were compared between a clear-cut and an adjacent forested site. Forest floor dry weights and nutrient contents were monitored for 28 months following the whole-tree harvest. Soil solution nutrient concentrations, temperature at a depth of 2.5 cm, and percent moisture in the top 10 cm of mineral soil were also monitored following cutting. Immediately following cutting, the forest floor was significantly heavier in the cut area due to logging residue, but after 28 months the clear-cut area forest floor had a dry weight of 10,500 kg/ha compared to 15,400 kg/ha in the uncut area. Following cutting, concentrations of NH4(+)-N, NO3(-)-N and K were higher in the soil solution of the cut area, whereas concentrations of P, Ca and Mg were similar in both areas. The higher concentrations in the clear-cut were attributed to more rapid decay of logging slash and forest floor material and reduced vegetative uptake. (Author's abstract)

POPULATION AND REPRODUCTIVE DYNAMICS OF NAIS COMMUNIS (OLIGOCHAETA: NAIDIDAE) FROM A WISCONSIN LIMNOCRENE,
Wisconsin Univ.-Milwaukee. Dept. of Zoology.
M. E. Smith.
American Midland Naturalist, Vol. 114, No. 1, p 152-158, July, 1985. 2 Fig, 1 Tab, 24 Ref.

Descriptors: *Limnocrenes, *Oligochaetes, *Population dynamics, *Reproduction, Wisconsin, Springs, Paratomy, Water temperature, Alkalinity, Hydrogen ion concentration, Biomass.

Population and reproductive dynamics of the oligochaete Nais communis were studied from August 1982 to November 1983 in a Wisconsin limnocrene (a spring discharging into a small basin which overflows into a stream channel). The study site was located in the township of Saukville, Ozaukee County. Naidids were found only among the large floating mats of Spirogyra which covered most of the limnocrene. Population density was significantly ($P < 0.05$) correlated with water temperature, total alkalinity and pH. Abundance peaks occurred during mid-August 1982 and early October 1983. No sexually mature worms were collected; asexual reproduction by paratomy took place throughout the study. Nais communis exhibited at most three zooids per chain; the majority of worms exhibited two zooids per chain when reproducing. There was no significant ($P > 0.05$) correlation of percentage of worms undergoing paratomy to environmental physico-chemical parameters and worm density. Mean doubling time for the field population of N. communis was 13.57 +/- 13.00 days. Seasonal changes in biomass were similar to those of abundance. (Moore-IVI)

SEASONAL CHANGES IN ABUNDANCE OF BROWN TROUT (SALMO TRUTTA) AND RAINBOW TROUT (S. GAIRDNERII) ASSESSED BY DRIFT DIVING IN THE RANGITIKEI RIVER, NEW ZEALAND,
Ministry of Agriculture and Fisheries, Wellington (New Zealand). Fisheries Research Div.
B. J. Hicks, and N. R. N. Watson.
New Zealand Journal of Marine and Freshwater Research, Vol. 19, No. 1, p 1-10, 1985. 1 Fig, 6 Tab, 17 Ref.

Descriptors: *Trout, *Seasonal variation, *Rangitikei River, *New Zealand, Drift diving, Fish, Abundance.

Numbers and approximate sizes of brown trout (Salmo trutta L.) and rainbow trout (S. gairdnerii Richardson) were estimated by snorkel divers at 6 sites in the middle reaches of the Rangitikei River, North Island, New Zealand, over 14 months. The results showed that different species and sizes of trout varied in abundance with time. The species of fingerling trout (6-12 cm FL) could not be identified because of their small size and shoaling behavior. Rainbow trout abundance varied seasonally and was greatest in January and April (between 18 and 60 fish per kilometer) when fish between 23 and 38 cm FL were the most abundant size class. Brown trout abundance showed much less variation with time (between 5 and 36 fish per kilometer at most sites). Also in contrast to rainbow trout, the majority of brown trout were > 38 cm FL, and in June, when the greatest density was observed (56 fish per kilometer), 70 redds were

seen at the same site. Two sites were dived within a 48 h period to test the variability of the method. Comparisons between the 3 dives at each site revealed no significant differences between the numbers of fish in different species and size classes. (Author's abstract)

NUTRIENT DEMAND AND AVAILABILITY AMONG PLANKTONIC COMMUNITIES - AN ATTEMPT TO ASSESS NUTRIENT LIMITATION TO PLANT GROWTH IN 12 CENTRAL VOLCANIC PLATEAU LAKES,
Department of Scientific and Industrial Research, Taupo (New Zealand). Div. of Marine and Freshwater Sciences.
E. White, K. Law, G. Payne, and S. Pickmere.
New Zealand Journal of Marine and Freshwater Research, Vol. 19, No. 1, p 49-62, 1985. 3 Fig, 5 Tab, 26 Ref.

Descriptors: *Limiting nutrients, *Phytoplankton, *Lakes, *New Zealand, Nitrogen, Phosphorus, Algal growth, Bioassays, Nutrient storage.

Water from 12 central volcanic plateau lakes in New Zealand was studied on 4 occasions (one in each season). Four assays of nitrogen demand and 3 for phosphorus were employed in an attempt to identify the nutrients limiting plankton growth. Orthophosphate turnover times chlorophyll, and a range of analyses for nitrogen and phosphorus were made in support of bioassays. Consideration was given to both statistical and biological interpretation of the assays. The study did not produce a clear guide to the assessment of nutrient limitation among natural plankton communities. The phosphorus bioassays assess depletion of storage products rather than the levels of phosphorus in cells at which growth becomes limited. The same is true for most of the nitrogen bioassays, with the added complication that the analytical procedures may be too insensitive to assess depletion of storage products. Some advance can be made in understanding the nutrient status of planktonic communities at least in these 12 lakes, because it is possible to assemble a package of bioassays and measurements with criteria which identify waters in which nutrient limitation by either nitrogen or phosphorus is not operative. The data indicate that the storage capacity for phosphorus is c. x5 the subsistence level, and that for nitrogen may be only c. x0.5. If the storage capacity for phosphorus is indeed an order of magnitude greater than that for nitrogen, then phosphorus storage products must be depleted to 10% of their maximum before phosphorus limitation of plant growth becomes a possibility. (Moore-IVI)

INVESTIGATION OF SAMPLING STRATEGIES FOR LAKE BENTHOS,
Canterbury Univ., Christchurch (New Zealand). Dept. of Zoology.
B. V. Timms.
New Zealand Journal of Marine and Freshwater Research, Vol. 19, No. 1, p 71-78, 1985. 1 Fig, 6 Tab, 27 Ref.

Descriptors: *Benthos, *Sampling, *Lakes, Seasonal variation, Lake Pearson, New Zealand, Line transects, Abundance, Population dynamics.

Lake benthos is difficult to sample to obtain accurate estimates of population parameters. Part of the apparent variation in community structure and abundance of macrobenthos between lakes is attributable to the different sampling strategies used. Sampling was carried at Lake Pearson, Canterbury, New Zealand monthly from August 1978 to July 1979 at 12 sampling stations. A comparison of 7 sampling options shows that spot samples and line transects are inadequate but that an augmented line transect is almost as good as stratified random sampling. Winter/early spring and summer samples are needed to account for seasonal variations in species richness and community biomass. Much less effort is required for an augmented line transect, therefore it is recommended for lake survey and management studies. If large species such as mussels occur, it should be realized that this program is inadequate to sample them and either numerous grabs are needed in one period or over a seasonal cycle, or some other sampler should be used. 2I. Water In Plants

EFFECTS OF WATER AND MINERAL NUTRIENT SUPPLY ON A DECIDUOUS AND AN EVERGREEN DWARF SHRUB: VACCINIUM ULIGINOSUM L. AND V. VITIS-IDAEA L.,
Lund Univ. (Sweden). Dept. of Plant Ecology.
P. S. Karlsson.
Holarctic Ecology, Vol. 8, No. 1, p 1-8, March, 1985. 6 Fig, 2 Tab, 51 Ref.

Descriptors: *Nutrients, *Minerals, *Water requirements, Plant growth, Fertilization, Soil properties, Climate, Precipitation, Roots, Evergreen shrubs, Deciduous shrubs.

At time of harvest, in response to fertilization, the deciduous Vaccinium uliginosum had accumulated more nutrients and grown more than the evergreen V. vitis-idaea. This study aimed at testing whether a similar response would be obtained in these species after fertilizing a site that differed from that used in the earlier study both in soil and climate characteristics. The present study was conducted at Abisko, northern Sweden, at a well drained site with a thin layer of organic soil, no permafrost, and relatively low annual precipitation. It is concluded that a sized response pattern cannot be expected for evergreen and deciduous species without considering other plant characteristics such as the amount of roots and (perhaps still more important) the spatial distribution of the roots in the soil. Such differences within a growth form group may be further accentuated by differences in climate, mainly precipitation, and soil quality between sites. The different response patterns recorded for V. vitis-idaea and V. uliginosum in the present study as compared to the earlier study may be result of such site differences. (Baker-IVI)

CANOPY TRANSPIRATION AND WATER FLUXES IN THE XYLEM OF THE TRUNK OF LARIX AND PICEA TREES - A COMPARISON OF XYLEM FLOW, POROMETER AND CUVETTE MEASUREMENTS,
Bayreuth Univ. (Germany, F.R.). Lehrstuhl fuer Pflanzenoekologie.
E. D. Schulze, J. Cermak, R. Matyssek, M. Penka, and R. Zimmermann.
Oecologia, Vol. 66, No. 4, p 475-483, July, 1985. 7 Fig, 1 Tab, 38 Ref.

Descriptors: *Canopy, *Transpiration, *Xylem, *Trees, *Larix, *Picea, *Porometers, Plant tissues, Plant physiology, Leaves.

Leaf gas exchange, transpiration, water potential and xylem water flow measurements were used in order to investigate the daily water balance of intact, naturally growing, adult Larix and Picea trees without major injury. The total daily water use of the tree was very similar when measured as xylem water flow at breast height or at the trunk top below the shade branches, or as canopy transpiration by a porometer or gas exchange chamber at different crown positions. The average canopy transpiration is about 12% lower than the transpiration of a single twig in the sun crown of Larix and Picea. Despite the similarity in daily total water flows there are larger differences in the actual daily course. Transpiration started 2 to 3 h earlier than the xylem water flow and decreased at noon before the maximum xylem water flow was reached, and stopped in the evening 2 to 3 h earlier than the water flow through the stem. The daily course of the xylem water flow was very similar at the trunk base and top below the lowest branches with shade needles. The difference in water efflux from the crown via transpiration and the water influx from the trunk is caused by the use of stored water. The specific capacitance of the crown wood was estimated to be 4.7 x 10 to the minus 8th power and 6.3 x 10 to the minus 8th power kg/kg/Pa and the total amount of available wate
was 17.8 and 8.7 kg, which is 24% and 14
total daily transpiration in Larix and Picea
tively. Very little water was used from
tree trunk. With increasing transpiration a
stored water from wood in the crown, t
potential in the foliage decreases. Plan
status recovers with the decrease of tran
and the refilling of the water storage a
liquid flow conductance in the trunk was
to the minus 9th power and 0.36 x 10 to t
9th power mol/sq m/s/Pa in Larix a
respectively. The role of stomata and thei

LIGHT REDUCTION AND MOISTURE STRESS: EFFECTS ON GROWTH AND WATER RELATIONS OF WESTERN LARCH SEEDLINGS,
Oregon State Univ., Corvallis. Coll. of Forestry.
N. C. Vance, and S. W. Running.
Canadian Journal of Forest Research, Vol. 15, No. 1, p 72-77, February, 1985. 4 Fig, 2 Tab, 30 Ref.

Descriptors: *Larch trees, *Water stress, *Plant growth, Solar radiation, Leaves, Water potential, Seedlings, Humidity, Conductance.

Ten-week-old western larch (Larix occidentalis Nutt.) seedlings were grown in a greenhouse under 70, 37, and 27% full sunlight from late July to early October. In August, seedlings under each light treatment were repetitively water stressed until predawn leaf water potential reached one of three levels: no stress (> -0.4 MPa), moderate stress (-0.7 to -1.0 MPa), and severe stress (-1.5 to -1.8 MPa). Moisture stressing significantly reduced height and diameter of seedlings grown under 70% light. Light reduction reduced shoot and root biomass accumulation. A positive linear relation was found between root dry weight and light intensity. The largest seedlings (on a weight basis) received the highest light, were unstressed, and had the lowest shoot/root ratios. Terminal bud set was not affected by light reduction or moisture stressing but occurred under a 14-h photoperiod and reduced nighttime temperatures. Stressed and shaded seedlings had significantly reduced diurnal leaf conductance (K1), and stress-cycled seedlings showed an adjustment to stressing. The K1 of unstressed seedlings was correlated with humidity deficit (ABHD), and K1 of stressed seedlings, with leaf water potential and ABHD. Maximum K1 declined with decreasing leaf water potential but not to a level indicating complete stomatal closure. (Author's abstract)

Trends of needle water potential and resistance to water uptake by Douglas-fir seedlings are compared to those for western and mountain hemlock. Soil-to-foliage flow resistance for various soil water potentials was calculated as the difference between soil and needle water potentials, divided by the corresponding water uptake rate. Needle water potential in western and mountain hemlock falls as the soil dries, but under the experimental conditions, it remained stable in Douglas-fir. Resistance to water flow from soil to foliage is higher for the hemlocks and increases more steeply as the soil dries. As the soil continues to dry, the effect of larger and more steeply increasing resistance, in hemlocks, is to decrease water uptake to near zero, long before the water potential difference becomes very small. This occurs although root surface area is much greater for the hemlocks than for Douglas-fir, and is especially pronounced for mountain hemlock. (Moore-IVI)

HYDROLOGY OF MID-ALTITUDE TUSSOCK GRASSLANDS, UPPER WAIPORI CATCHMENT, OTAGO. I. EROSION, SEDIMENT YIELDS AND WATER QUALITY,
New Zealand Forest Service, Rotorua. Forest Research Inst.
C. L. O'Loughlin, L. K. Rowek, and A. J. Pearce.
Journal of Hydrology (New Zealand), Vol. 23, No. 2, p 45-59, 1984. 6 Fig, 4 Tab, 16 Ref.

Descriptors: *Soil erosion, *Sediment yield, *Water quality, *Grasslands, *Otago, *New Zealand, Temperature effects, Turbidity, Bank stabilization, Catchment area, Hydrology.

A study was designed to determine the erosion status of catchments under lightly modified tussock grassland and to examine the export of sediment from the catchment. The quality of the catchments' streamwater was also considered. Sediment yields from two small tussock catchments underlain by schist bedrock in the East Otago uplands South Island, New Zealand, were 42.8 cubic m and 12.6 cubic m respectively during a 4 year period of study. The area appears to have low erosion rates, as evidenced by the sediment yield rates. Surface erosion and mass wasting were not common occurrences on the catchments' slopes. Most of the sediment delivered to the streams derived from channel scouring and bank collapse during large floods. Suspended sediment concentrations ranged from less than 2 mg/l to 430 mg/l and the streamwaters remained clear at less than 15-20 mg/l sediment concentration for about 97% of the time. Stream pH averaged 6.8, stream conductivity ranged from 12.4 to 54.8 micro-S/cm and stream temperature ranged between maxima of 16 to 19 degrees C in summer and minima of 0-3 degrees C in winter. SOME THOUGHTS ON FINE-GRAINED SEDIMENT TRANSPORT AND DEPOSITION,
University of Southern California, Los Angeles. Dept. of Geological Sciences.
D. S. Gorsline.
Sedimentary Geology, Vol. 41, No. 2/4, p 113-130, December, 1984. 118 Ref.

Descriptors: *Sediment transport, *Deposition, Sedimentation, Particulate matter, Plankton, Marine environment.

Some aspects of fine-grained sedimentary research are reviewed. Water circulation is instrumental in determining the distribution of these particulates. Planktonic biologic filtering, aggregation, and reworking are of primary importance in deposition. Early diagenesis is controlled by bacterial processes with consequent changes in bulk and chemical properties. Initial deposition of most fine particulates is in the continental margins and then it moves to deep-ocean floors by mass wasting and high concentration flows. The stability of these fine deposits even on slopes of gentle gradient is controlled primarily by water content which, in turn, is a function of sedimentation rate and texture of the supply. Mass transport can occur in a variety of forms from slow creep to catastrophic failures of large scale. The various forms of movement can cause a sequence of morphologies. Most of the fine-grained stratigraphic record urgently needs reevaluation and restudy. Models of paleogeographic reconstructions on a large scale need to include the results of physical and biological oceanographers as the older simpler scenarios of locations of zones of high bioproductivity and of the patterns of major ocean currents have been greatly modified in recent studies. CHANGES IN SEDIMENT COMPOSITION DURING SEASONAL RESUSPENSION IN SMALL SHALLOW DIMICTIC INLAND LAKES,
Wisconsin Univ.-Platteville. Dept. of Geosciences.

E. B. Nuhfer, and R. Y. Anderson.
Sedimentary Geology, Vol. 41, No. 2/4, p 131-158, December, 1984. 13 Fig, 5 Tab, 36 Ref.

Descriptors: *Resuspension, *Sedimentation, *Lake sediments, Edinboro Lake, Pennsylvania, East Twin Lake, Ohio, Kettle lakes, Chemical analysis, Calcium, Phosphorus, Sulfur, Magnesium, Sodium, Zinc, Nickel, Chromium, Manganese, Iron, Aluminum, Seasonal variation.

Results are presented of resuspension studies at two small shallow kettle lakes, Edinboro Lake, Pennsylvania, and East Twin Lake, Ohio. These lakes have significant amounts of seasonal resuspension and measurable accompanying variations in seston with respect to chemistry, mineralogy, and petrography. The objectives of the work were to study the magnitude and duration of resuspension events; and to acquire sufficient chemical, mineralogical, and petrographic data from an annual record to permit both detection of seasonal variations and statistical analyses of relative importance of detected variations. Resuspension in the lakes occurs from both seasonal holomictic circulation and from continual entrainment of material from the shallow portions of the lake by the circulating epilimnion. Trapping rates were only negligibly affected by rainstorms. These rates varied widely throughout the year with minimum sedimentation rates noted at time of winter ice cover, and maximum rates noted during autumn circulation. Most material collected by the sediment traps was resuspended from the lake bottom. The only inactive time for resuspension was the time period under winter ice cover. Compositional variations included enrichment of Si in winter, Ca, P, S, Mg, Na, Zn, Ni, and Cr in summer, and Mn in late summer and autumn. During times of reduced circulation the sediment is generally enriched in amorphous mineraloids and during spring and autumn, in detrital minerals. Endogenic minerals include calcite, pyrite, and possibly some kaolinite. Most of the mineral fraction is detrital. Trap sample differs in composition from bottom sediment, but samples collected in traps in early winter closely resemble bottom material. Traping rates in early winter appear closest to true rates of fill. (Baker-IVI)

FURTHER EVIDENCE OF FINE-GRAINED SEDIMENT DISPERSAL IN THE SOUTHEASTERN YELLOW SEA,
Seoul National Univ. (Republic of Korea). Dept. of Oceanography.
S. K. Chough.
Sedimentary Geology, Vol. 41, No. 2/4, p 159-172, December, 1984. 8 Fig, 31 Ref.

Descriptors: *Sedimentation, *Dispersion, *Yellow Sea, China, Korea, Yangtze River, Hwangho River, Keum Estuary, Kaolinite, Chlorite, Mineralogy, Sediment transport.

The Yellow Sea is a shallow, post-glacially submerged epicontinental basin, a tectonically stable depocenter of clastics derived from the adjoining land masses of China and Korea. Sediments in the Yellow Sea are fine-grained in the broad western part, where they are derived mainly from the Chinese rivers, the Hwangho and Yangtze, and coarse-grained in the narrow eastern part originating largely from the Korean Peninsula. The coarse grained sediments near the Keum Estuary contain subtantial amounts of fine fractions. Kaolinite and chlorite are abundant in the fine fractions for about 120 km both toward the northwest and the southwest. Trace elements distributed in the bulk sediments follow the same trends. The close correspondence between mineralogical and geochemical evidence and hydrographic data suggests that the bulk of fine-grained sediments in the southeastern Yellow Sea originates from the Keum River and is subsequently transported by prevailing nearshore currents both northwestward during summer and dominantly southwestward in winter. Illite is dominant in the rest of the sea as influenced by discharge of Hwangho River and possibly also the Yangtze. There appears only to be a minimal effect from the Kuroshio discharging into the southeastern Yellow Sea. (Baker-IVI)

SOIL EROSION MEASUREMENT AND SOIL CONSERVATION RESEARCH IN CULTIVATED AREAS OF THE UK,
National Coll. of Agricultural Engineering, Silsoe (England).
R. P. C. Morgan.
Geographical Journal, Vol. 151, No. 1, p 11-20, March, 1985. 7 Tab, 62 Ref.

Descriptors: *Soil erosion, *Soil conservation, *Erosion control, *England, *Cultivated lands, Rill erosion, Wind erosion, Slope, Soil types.

Agricultural soil erosion by both water and wind is a local scale problem in the UK, particularly on the sandy loam soils under continuous cereal production or market gardening in the midland and eastern counties of England. Mean annual rates of soil erosion by water on these soils in fields on hillslopes up to 11 degrees can exceed 2 kg/sq m when rilling occurs, compared with a rate for top soil renewal of only about 0.1 kg/sq m. Rates as high as 1.9 kg/sq m have been recorded in individual storms and storm rates greater than 0.2 kg/sq m can occur as frequently as in four years out of seven. Storm losses by wind erosion are of similar magnitude but those for gully erosion are much higher with rates reaching 15 to 19 kg/sq m in single storms. Research into soil conservation has been carried out on Experimental Husbandry Farms and by farmers and commercial organizations with a direct interest in the problem. It has been largely limited to the use of shelterbelts, guard crops, soil stablizers and land imprinting or pressing to control wind erosion with virtually no work having been undertaken on water erosion control. There is a need for more fundamental research which will allow the mechanics of the control measures to be understood better and to enable their general applicability to be assessed more readily. Research projects with these aims in mind are described involving investigations of the effects of crop cover on splash erosion, tillage effects on soil erodibility and the simple modelling of the erosion system to predict the stability or instability of the soil resource under given systems of agricultural management. SOIL EROSION AND SEDIMENT TRANSPORT RESEARCH IN TROPICAL AFRICA,
International Inst. of Tropical Agriculture, Ibadan (Nigeria).
R. Lal.
Hydrological Sciences Journal, Vol. 30, No. 2, p 239-256, June, 1985. 3 Fig, 3 Tab, 107 Ref.

Descriptors: *Soil erosion, *Erosion, *Sediment transport, *Africa, *Research, Sediment load, Land use, Deforestation, Environmental protection.

The magnitude of soil erosion in tropical Africa is reviewed and related to erodibility, erosivity and landform in different ecological regions. There are few direct measurements of erosivity and erodibility in tropical Africa and the relevance of using the Universal Soil Loss Equation in estimating these parameters is reviewed. Soil erodibility is not a fixed parameter and changes with time. Although localized rates of soil erosion can be high, the erosion rates derived from sediment loads in rivers are often low. Most of the available data on sediment loads of African rivers are 10-20 years old, and little research information is available on the delivery ratios associated with different catchments. Rapidly changing land use is one of the major factors responsible for accelerated soil erosion, and the effects of deforestation, grazing, fire, and of cultural practices are discussed. The economics of soil erosion is reviewed in terms of loss in productivity and siltation of reservoirs. Research and development needs are listed. (Author's abstract)

uspended particles, and the contami- ted with them, undergo episodic heir downstream migration and do follow the water motion. Below the NY, the suspended sediment trans- tially modified by tidal resuspension agglomeration. Samples taken sea- tations had an average concentration anging from 28 mg/l during low freshwater discharge to 40 mg/l at times of high discharge. The concentrations were increasingly controlled by tidal resuspension towards the month where tidal discharges are typically 20 times the freshwater discharge. The average percentage weight loss on ignition was 22%. Measurements of the particle-size distributions in both undisturbed and disaggregated samples showed that suspended particles were usually mineral-organic aggregates. In contrast to resuspension which increases the time particles spend in the water column, agglomeration tends to decrease that time by increasing the settling velocity. Most of the fine-grained sediment distribution occurs in the geochemical estuary and a substantial amount of this sediment is ultimately dredged and disposed in the ocean. (Author's abstract)

Descriptors: *Pyrite, *Sediments, *Carbon/sulfur ratio, Lake sediments, Redox status, Volatile compounds, Sulfur.

The vertical distribution of pyrite, acid volatile sulfide (AVS), carbon, and total S (St) were determined directly in the sediments of three lakes of different trophic status. The results showed that freshwater pyrite formation reflects the redox status of the sediment of overlying waters. It appears to form chiefly in reducing sediments which are subject to oxidizing influences, by either a low turnover of organic carbon or periodic incursions of oxygen. Although there are high concentrations of AVS in the near-surface sediments of productive lakes, very little is diagenetically converted to pyrite. The feasibility of using sulfur ratios to diagnose whether rocks were formed in marine or freshwater environments is assessed. New values for FeS2/S of 0.5-5 show that this ratio does not provide a reliable test. Values of C/Sp, where Sp represents pyrite sulfur, lie within the range of 160-700 and are much higher than previously measured ratios of C/St of 1-50. These new determinations show that, if pyrite sulfur is unequivocally measured, C/S ratios may be a more sensitive indicator of salinity than had been previously thought. (Author's abstract)

Descriptors: *River beds, *Topography, *Mathematical models, Bed load, Sediment transport, River mechanics, River morphology.

Mathematical models are being developed at the Delft Hydraulics Laboratory for the computation of time-dependent, two-dimensional bed deformation in alluvial rivers. A most promising verification of the predictive capacity of one such model has been obtained for the Waal River in the Netherlands. This model was developed for rivers with dominant bed load transport without significant grain-sorting effects and with approximately constant width. Also, some results of computations with variable boundary conditions are given which simulate the effect of the river regime and the extraction and return of cooling water on the bed topography. BRAHMAPUTRA RIVER, ASSAM, INDIA: PHYSIOGRAPHY, BASIN DENUDATION, AND CHANNEL AGGRADATION,
Johns Hopkins Univ., Baltimore, MD. Dept. of Geography and Environmental Engineering.
D. C. Goswami.
Water Resources Research, Vol. 21, No. 7, p 959-978, July, 1985. 18 Fig, 6 Tab, 61 Ref.

Descriptors: *Brahmaputra River, *India, *Physiography, *Aggradation, *Erosion, Sediment transport, Suspended sediments, Sediment load, Channels, Himalayas, Geology.

The Brahmaputra River in Assam, India, characterized by high seasonal variability in flow, sediment transport, and channel configuration, experienced a secular period of aggradation from 1971 to 1979. The suspended load budget indicates an overall aggradation of the 607-km Assam reach of the Brahmaputra by about 16 cm during that period, with about 70% of the suspended sediment inflow into the reach being retained in the channel. Expressed as a percentage of the change in storage for the different reaches, computed errors due to sampling variability in sediment discharge generally lie within about 5-15% and do not appear to be large enough to affect the conclusions drawn from the suspended load budget. For a 145-km reach of the Brahmaputra, an alternative method based on measurement of channel cross sections suggests 21 cm of aggradation, somewhat more than estimated by the suspended load budget. Based on the suspended load carried by trans-Himalayan rivers, the present rate of denudation of the eastern Himalayas is estimated to be 73-157 cm/1000 years. The average rate for the last 2-3 million years, estimated from the volume of alluvial fill in the Brahmaputra valley in Assam, the sediment yield of the Himalayan rivers, and assuming a total yield to deposition ratio of 1.4 (present study), is 3 cm/1000 years. The current high rate of denudation of the Himalayas may be attributed mainly to the rapid uplift of the mountain system, recent earthquake activity, and high susceptibility of geologic formations to erosion by running water coupled with the effectiveness of the monsoon rainfall regime. SHORELINE EVOLUTION ALONG THE NORTHERN COAST OF THE GULF OF MEXICO,
Louisiana State Univ., Baton Rouge. Dept. of Geology.
D. Nummedal, R. F. Cuomo, and S. Penland.
Shore and Beach, Vol. 52, No. 1, p 11-17, January, 1984. 12 Fig, 30 Ref.

Descriptors: *Erosion, *Coastal waters, *Shores, *Gulf of Mexico, *Louisiana, Sedimentation, Barrier islands, Sea level, Water level.

The change in position of the sedimentary shoreline along the coastal waters of Louisiana over time is a function of the relative rates of sedimentation and sea level change. The morphology and evolutionary history of barrier islands along the northern coast of the Gulf of Mexico clearly document how differences in the rates of sea level rise and sediment supply controls shoreline evolution. The development on the Mississippi deltaic plain in Louisiana has been one of episodic delta progradation, abandonment, and wave reworking of fluvial distributary sand bodies to generate flanking barrier islands. The central headlands have retreated by surface erosion; on the flanks a set of regressive barriers developed as long as they could be sustained by sediment supply from the eroding updrift headland. Rapid local relative sea level rises ultimately remove the source from the transport system. At that time, the flanking regressive barriers are drowned by the rising sea; the transgressive barriers on the central headland are probably removed by sustained shoreface retreat. Provided there is enough sand on the upper delta plain, a new cycle of barrier island development may be initiated. Rapid sea level rise facilitates the drowning of major coastal barriers and sudden, dramatic landward shifts in the shoreline. Slower rates of sea level rise permit the local development of large regressive sequences as long as sediment supply is present. The ultimate fate of the shoreline under this regime appears to be shoreface erosion of nearly the complete coastal depositional sequence. (Baker-IVI)

COASTAL EROSION IN PUERTO RICO,
Puerto Rico Univ., Mayaguez. Dept. of Marine Sciences.
J. Morelock.
Shore and Beach, Vol. 52, No. 1, p 18-27, January, 1984. 21 Fig, 4 Ref.

Descriptors: *Puerto Rico, *Erosion, *Coasts, Erosion control, Aerial photography, Beach erosion, Accretion, Flood control.

Using a series of aerial photographs from 1936, 1950-51, 1962-63, 1971, and 1977, ten sites of severe coastal erosion in Puerto Rico were studied. El Tuque Park is a public beach west of Ponce. From 1971 to 1977 the straightened shoreline at the most rapidly eroding sites had a rate of erosion of 1.7 m/yr, which compares favorably with the rate of loss of shoreline at this point from 1962 to 1971 which was 7.2 m/yr. At Playa Cortada the present pattern of erosion poses a problem for houses that were built at the waterfront east of the old pier. Aguada has a beach which is a partial foreshore that terminates in an eroding cliff reached by high wave conditions. The period of accretion from 1937 to 1950 may have been caused by an influx of flood sediments. Between 1950 and 1977 there has been a loss of 25 m of shoreline, and the rate of erosion has been increasing. The area has changed from a developed beach profile to the partial foreshore as erosion moved inland and cut into higher ground. At Punta Salinas major modifications have been carried out. The Bayamon River has been closed off from discharge into the bay and flood control channels and jetties have been built to stem the tide of erosion. Isla Cabras, prior to 1971, gave no signs of erosional changes in the shoreline. Between 1971 and 1977, however, there is a drastic change at the southeast corner of the island with erosion occurring at a rate of 3.35 m/yr. Arecibo showed 35 m of shoreline retreat in the southern part of the bay between 1940 and 1959 for an annual rate of 1.7 m. The 1962 to 1971 photographs showed a moderate rate of erosion at the point of Punta Iglesia and a rate of 1.7 m/yr of eroding north of the sand borrow pit. Findings are also presented for Punta Uvero, Boca de Cangrejos, Pozuela, and Law Mareas. A program was recommended in 1978 which called for the classifying of the shoreline in terms of erosion hazard as a corollary to the flood warning classification of coastal areas. (Baker-IVI)

NEWLY DISCOVERED EVIDENCE FROM THE SAN DIEGO COUNTY AREA OF SOME PRINCIPLES OF COASTAL RETREAT,
Scripps Institution of Oceanography, La Jolla, CA.
G. G. Kuhn, and F. P. Shepard.
Shore and Beach, Vol. 51, No. 1, p 3-12, January, 1983. 20 Fig, 25 Ref.

Descriptors: *Erosion, *San Diego County, *Califonia, Erosion control, Flood control, Shores, Coastal waters, Beach erosion, Breakwaters, Groundwater.

The study of coastal changes of San Diego County has thrown some light on coastal erosion along shoreline areas of moderate relief. The development of the breakwater at the entrance of San Diego Bay has demonstrated the importance of beach erosion in the vicinity of the Hotel Del Coronado. Artificial shoreline protection has become necessary in this same vicinity to forestall erosion where huge condominiums have recently been constructed on the sand. The study of Oceanside and areas to the south showed that the general interpretation of the dominance of southflowing sediment-transporting currents is not always applicable. Groundwater must have dissolved the calcareous sandstone cement along remnant shear zones in the Solana Beach area, producing caverns which weaken adjacent cliffs. The high cliffed area from Torrey Pines south to La Jolla show the importance of groundwater, accentuated by man's activities, and huge landslides. The low alluvial cliffs in the vicinity of Scripps Institution show the importance of changing weather cycles and coastal erosion since wide beaches develop during quiet periods with little cliff retreat and give a false sense of security to building sites along the bluff edges. Descriptors: *Ozone, *Reaction kinetics, *Inorganic compounds, *Free radicals, Sulfur compounds, Chlorine compounds, Nitrogen compounds, Water treatment, Chemical reactions.

The kinetics of reactions of aqueous ozone with inorganic species are of interest for the understanding of a wide variety of systems: ozone interactions in atmospheric cloudwater or urban fog; ozone impinging onto the sea surface; and drinking and cooling water treatment. Second-order rate constants are reported for reactions of ozone with 40 inorganic aqueous solutes. Included are compounds of sulfur (e.g. H2S, H2SO3, HOCH2SO3H), chlorine (e.g. Cl(-), HOCl, NH2Cl, HClO2, ClO2), bromine (e.g. Br(-), HOBr), nitrogen (e.g. NH3, NH2OH, N2O, HNO2) and oxygen (e.g. H2O2), as well as free radicals (e.g. O2(-), OH). Most of these compounds exhibit an increase in rate constant with increasing pH corresponding to their degree of dissociation. Rate constants are based on ozone consumption rates measured by conventional batch-type or continuous-flow methods and determinations of stoichiometric factors. Also listed are data determined by pulse-irradiation techniques using kinetic spectroscopy. Ozone reacts rapidly with many oxidizable inorganic aqueous solutes. Many of them are strongly or fully protected when the site of reaction becomes protonated; most inorganic acids are only reactive in their dissociated form. Ammonia also only reacts when not protonated. Therefore, at pH values below the pKa of the site of the reaction, the rate constants of such solutes generally decrease by a factor of 10 per pH decrement. (Moore-IVI)

Descriptors: *Radon, *Groundwater, *Spatial distribution, Precipitation, Pumping, Geology, Seasonal variation, Sampling, Wells, Japan.

The spatial and vertical distributions of Rn-222 concentration in unconfined groundwater were surveyed, and the change of the concentraiton in groundwater relative to pumping was studied. The daily change of radon concentration in groundwater was observed and the effect of precipitation on the concentration was examined. The surveyed area is located at the Research Reactor Institute of Kyoto University (Japan). Spatial distribution of radon concentrations in groundwater in the limited area of less than 200 sq m showed rather large variation, ranging from about 170 to 300 pCi/l. This may stem from differences in geology, as the boreholes which show the higher concentration of 250-300 pci/l are close to each other. The high values may be due to small differences in the volume of water withdrawn during sampling. Vertical distributions of concentration increase in unconfined groundwater were clearly obtained in summer rather than in winter due to the stability of water density, although the spatial distributions of concentration were observed in a restricted area. The extraction of groundwater leads to about a two-fold increase in the radon concentration compared with the initial value in the borehole. A steady state concentration is reached after the extraction of about 1 cu m of water. Thus it is necessary to pump more than 1 cu m to obtain a representative concentration of the steady state in unconfined shallow groundwater. A decrease in radon concentration caused by dilution by precipitation was observed when the groundwater level rises more than about 50 cm, whereas radon content increased after small rains because the water in the well could exchange with fresh groundwater. The concentration diluted by the precipitation recovers to the former level within a week. (Moore-IVI)

PHOSPHORUS FORMS AND CONTENT IN NATURAL WATER AND FACTORS DETERMINING ITS CYCLING,
Akademiya Nauk SSSR, Moscow. Inst. Vodnykh Problem.
N. G. Dmitrieva, and L. O. Einor.
Water Resources, Vol. 11, No. 4, p 360-370, July-August, 1984. 80 Ref. Translated from Vodnye Resursy, No. 4, p 110-120, July-August, 1984.

Descriptors: *Phosphous, *Natural waters, *Cycling nutrients, Lakes, Rivers, Runoff, Precipitation, Bottom sediments, Water analysis, Organic compounds, Aquatic life.

The formation of the quality of natural water in many respects is determined by the characteristics of hydrochemical and biochemical processes which depend on the effect of a number of factors within and outside of water bodies. The main pools of phosphorus compounds are the water itself, bottom sediments, and biota. The sources of inflow of phosphorus into water objects are the allochthonous runoff, precipitation, groundwater runoff and other factors. The anthropogenic factors of entry of phosphorus into water bodies and streams has become a powerful factor even increasing in significance. Phosphorus is present in surface waters of continental water bodies primarily in an organic form namely, in the composition of living organisms and in particles of dead material suspended in water or settled on the bottom, and in water in the form of soluble organic matter. Balance calculations of the income and outgo of P in various bodies of water is of great value, especially for predicting their state, but is an extremely difficult scientific problem. For its solution it is necessary to have a sufficiently complete and accurate data bank on all components of the phosphorus balance and their changes during a number of years. The calculations can be made as the final step of a quantitative study of sources of the inflow, accumulations, and removal of all P forms. (Baker-IVI)

GROUND-WATER QUALITY IN WYOMING,
Geological Survey, Cheyenne, WY. Water Resources Div.
L. R. Larson.
Available from OFSS, USGS Box 25425 Lakewood, CO 80225. USGS Water-Resources Investigations Report 84-4034, 1984. 71 p, 55 fig, 2 tab, 18 ref.

Descriptors: *Water quality, *Groundwater, *Aquifer, *Dissolved solids, Nitrates, Fluorides, Trace elements, *Wyoming.

This report graphically summarizes ground-water quality from selected chemical-quality data for about 2,300 ground-water sites in Wyoming. Dissolved-solids, nitrate, fluoride, arsenic, barium, cadmium, chromium, lead, mercury, selenium, iron, and manganese concentrations are summarized on a statewide basis. The major chemical-quality problem that limits the use of Wyoming ground-water is excessive dissolved-solids concentrations. The aquifers with the best quality water, based on the lowest median dissolved-solids concentration of water in aquifers with 20 or more sampled sites, are Holocene lacustrine deposits, the upper Testiary Ogallala Formation and Arikaree Formation, and the Mississippian Madison Limestone. The counties with the best quality water, based on the lowest median dissolved-solids concentrations are Teton County and Laramie County. Hot Springs County and Natrona County have the highest median dissolved-solids concentrations. About 3 percent of the nitrate concentrations of ground-water samples exceeded the national primary drinking-water standard of 10 milligrams per liter. Fluoride concentrations exceeded the national primary drinking-water standard in 14 percent of the ground-water samples. Except for selenium, toxic trace elements generally have not been found in concentrations in excess of the drinking-water standards. About 19 percent of the iron and about 30 percent of the manganese concentrations in ground-water samples exceeded the national secondary drinking-water standards. (USGS)

COMPUTER SIMULATIONS OF THE FRASER RIVER PLUME,
Dalhousie Univ., Halifax (Nova Scotia). Dept. of Oceanography.
L. Royer, and W. J. Emery.
Journal of Marine Research, Vol. 43, No. 2, p 289-306, May, 1985. 7 Fig, 35 Ref. Canadian Natural Sciences and Engineering Research Council Strategic Grants Program for Oceans grant G0353.

Descriptors: *Computer models, *Plumes, *River mouth, *Fraser River, *Straight of Georgia, *British Columbia, *Salinity, Wind-driven currents, Wind velocity, Tidal effects, Water currents, Stream discharge.

Instruments sampling the engine cooling water on two B.C. ferries were used to monitor the temporal and spatial variations of the Fraser River Plume, in the central Strait of Georgia (British Columbia) for nearly two years. Travelling along two different routes north and south of the river mouth, each ferry provided eight horizontal near-surface salinity transects per day. From each transect, the arithmetic average salinity along the section (denoted southern or northern section average salinity) was extracted, formulated as a time series of hourly or daily values and then compared to equivalent computer simulated series. A numerical model, previously developed to examine the effect of tidal forcing on the plume, was modified to include as inputs the hourly wind and daily discharge data. Average model salinities along the ferry section were computed and compared to the observed ferry data. Good agreement was reached after manipulating the entrainment velocity and the momentum transfer from the wind to the plume. The tides were seen to add a relatively small tidal modulation to the general salinity pattern resulting from the combined effects of wind and discharge. (Author's abstract)

Descriptors: *Coastal waters, *Lagoons, *Tidal waters, Rhode Island, Charlestown Lagoon, Block Island Sound, Model studies, Finite element method, Hydrodynamics, Model studies.

The integration of a field observation program and hydrodynamic modeling studies are described. A better understanding of the pond circulation dynamics and exchanges of water with the ocean is derived through this integration. The Charlestown lagoon system, located on the southern coast of Rhode Island, consisting of two major basins, Ninigret Pond and Green Hill Pond, served as the study area. The pond system studied responds to first order in a simple pumping mode with the pond water levels rising and falling uniformly throughout in response to offshore forcing. At the semidiurnal tidal frequencies, where most of the energy is located, the sea level response factor is 0.18 with a high water phase shift of 2.5 hr. As the frequency of the forcing function decreases the response factor increases and the phase shift decreases until at periods greater than 4-5 days the water level variations in side and outside the pond are identical in phase and amplitude. The hydrodynamic model predictions for M2 tidal forcing, using the simple inlet hydraulics method of representing the system, are in good agreement with data and also compare well to measurements derived from lab experiments on a simple ocean-inlet bay system. While the geomagnetic electrokineograph (GEK) data provided reasonable estimates of the tidal currents in the breachway its low frequency response was particularly poor. The primary source of long term signal drift in GEK systems is that caused by variation of electrode temperature. A second significant drift source is the random variations which occur in the basic electrochemical potentials of the electrodes themselves. A third source is the telluric potentials which occur at both low and high frequencies. In extreme situations, continuous conductivity monitoring may be required. (Baker-IVI)

Descriptors: *Estuarine environment, *Sediments, *Groundwater movement, *Phosphates, Seagrass, Seepage, Interstitial water, Tidal effects, Indian River, Florida.

Factors influencing the spatial and short term temporal variability inherent in seepage meter measurements and how these measurements relate to variations of selected pore water nutrient concentrations were investigated using the Indian River, a narrow estuarine lagoonal system extending approximately 182 km along the east coast of Florida as the study site. How much of the total flux for dissolved reactive phosphate can be attributed to seepage in nearshore estuarine sediments was determined. The extent of short term dilution effects on sediment pore water was measured. In situ samplers and seepage meters located in the grass beds yielded results very different from the control sampler and meter in the nongrass area of the study site. The variation in seepage velocities and DRP flux rates within a small area of nearshore sediment was closely linked with the heterogeneity of the system. Sediment size analysis of cores collected adjacent to the in situ samplers in the seagrass bed indicated the highest percentage of particles to be in the 150 micro-m range. A higher percentage of these particles was present in the area with no seagrass. The study indicates that the continual movement of groundwater from the sediments of nearshore estuarine areas and the inherent variability of the system is an extremely important factor when considering the total flux of nutrients in a specific area. The effect of the tide, in this case, was to alter the hydraulic gradient. The relationship between groundwater seepage velocity and dissolved reactive phosphate flux in nearshore sediments and its dependence on hydrogeological variables is important in determining nutrient flux budgets. The apparent relationship between tidal height and seepage velocities needs more careful examination and may be even more dramatic in areas with greater tidal ranges. (Baker-IVI)

Descriptors: *Nutrients, *Estuarine environment, *Ponds, *Algal growth, Fertilization, Water pollution effects, Aquatic plants, Macrophytes, Solar radiation, Phytoplankton, Epiphytes.

Large experimental estuarine ponds were used to investigate the effects of nutrients on submersed vascular plant communities. The possibility that the decline in these plant communities as a result of fertilization can be explained in terms of increases in epiphytic algal and planktonic biomass which decrease the available light to leaves for macrophyte productivity was investigated. Seston and phytoplankton chlorophyll a increased with fertilization, and pronounced algal blooms were evident under high dosage. Of the total seston, phytoplankton exerted the greatest influence on attenuation of photosynthetically active radiation, such that there was insufficient light for submersed vascular plant growth at the sediment surface during blooms. An extensive epiphytic community developed on plants in all nutrient treated ponds at densities similar to those observed in nature on senescent plants. At high nutrient treatments the accumulation of epiphytic material resulted in over 80% attenuation of the incident radiation at the leaf surface. Biomass of submersed macrophytes decreased significantly under high and medium nutrient treatments compared to control and low treatments within 60 days following initial fertilization. Apparent production of vascular plants was reduced at the higher nutrient treatments. Most of this reduction was explained by attenuation of PAR associated with epiphytic material. Without PAR attenuance in the overlying water, observed levels of epiphytic growth would be insufficient to reduce light below compensation levels needed to

sustain vascular plant growth. At the high fertilization rates, integrated primary production of pond communities was significantly reduced with the loss of the vascular plants, even though phytoplankton and epiphytic growth were enhanced. (Baker-IVI)

EFFECTS OF PH AND PLANT SOURCE ON LIGNOCELLULOSE BIODEGRADATION RATES IN TWO WETLAND ECOSYSTEMS, THE OKEFENOKEE SWAMP AND A GEORGIA SALT MARSH,
Georgia Univ., Athens. Dept. of Microbiology.
R. Benner, M. A. Moran, and R. E. Hodson.
Limnology and Oceanography, Vol. 30, No. 3, p 489-499, May, 1985. 4 Fig, 33 Ref. NSF grants OCE81-17834, BSR 81-14823, BSR 82-15587 and NOAA, Office of Sea Grant grant NA 80AA-D00091.

Descriptors: *Georgia, *Okefenokee Swamp, *Sapelo Island, *Salt marshes, *Wetlands, *Hydrogen ion concentration, *Lignocellulose, *Biodegradation, Lignin, Isotope studies, Sediments, Microorganisms.

The microbial mineralization of synthetic C-14 labeled lignin, specifically radiolabeled (C-14 lignin)-lignocellulose and (C-14 polysaccharide)-lignocellulose from a variety of aquatic herbaceous and woody plants was investigated in water and sediment from a salt marsh on Sapelo Island, Georgia, and from the Okefenokee Swamp, an acidic peat-forming freshwater swamp in southern Georgia. Rates of microbial degradation of lignocellulose were depressed in the Okefenokee relative to those in the salt marsh. About 50% of the difference in mineralization rates was attributable to the low ambient pH (3.9) of Okefenokee water relative to the pH of salt marsh water (pH 7.1). Rates of mineralization of the lignin component of lignocellulose were only minimally affected within the range of pH 4-8, whereas mineralization of the polysaccharide component increased severalfold with increasing pH. Differences in the biodegradability of the various lignocelluloses were also observed; lignocelluloses from herbaceous plants were mineralized several times faster than lignocellulose from wood. NITROGENOUS NUTRIENT UPTAKE, PRIMARY PRODUCTION, AND SPECIES COMPOSITION OF PHYTOPLANKTON IN THE CARMANS RIVER ESTUARY, LONG ISLAND, NEW YORK,
State Univ. of New York at Stony Brook. Marine Sciences Research Center.
E. J. Carpenter, and S. Dunham.
Limnology and Oceanography, Vol. 30, No. 3, p 513-526, May, 1985. 16 Fig, 3 Tab, 26 Ref. NOAA Office of Marine Pollution Assessment grant NA 80-RAD0062, and NSF grant OCE 82-14764.

Descriptors: *Nitrogen, *Nutrients, *Primary production, *Species composition, *Phytoplankton, *Carmans River Estuary, *Long Island, *New York, *Estuarine environment, Ammonium, Nitrates, Urea, Cycling nutrients, Seasonal variation.

Uptake of NH4(+), NO3(-), and urea was measured at four stations in a small temperate-zone estuary over a 10-month period. Considering all four stations, NO3(-) accounted for 45% of all N taken up, followed by NH4(+) (43%) and urea (12%). Nitrogen uptake was highly temperature-dependent (r = 0.82), and an exponential relationship was apparent. Recycling was very important as a source of nitrogen, and mean NH4(+) pool turnover times were rapid, ranging from 4.3 to 6.8 h in the lower estuary in summer. PN turnover times in the lower estuary were also rapid, averaging 28.8 h in summer and being as short as 3.1 h in July and August. An analysis of N uptake using the relative preference index (RPI) indicated that NH4(+) was the preferred nutrient. However, high NO3(-) concentrations appeared to override the repressive effect of NH4(+) concentrations on nitrate reductase, and NO3(-)uptake was significant even at relatively high NH4(+) concentrations. Urea uptake did not appear to be affected by NH4(+) concentration. (Author's abstract)

DISTRIBUTION, ABUNDANCE, AND GROWTH OF JUVENILE DUNGENESS CRABS, CANCER MAGISTER, IN GRAYS HARBOR ESTUARY, WASHINGTON,
Washington Univ., Seattle. School of Fisheries.
B. G. Stevens, and D. A. Armstrong.
Fishery Bulletin, Vol. 82, No. 3, p 469-483, July, 1984. 9 Fig, 6 Tab, 23 Ref. Army Corps of Engineers contracts DACW-67-80-C-0086 and DACW-67-81-M-1096.

Descriptors: *Crabs, *Distribution, *Grays Harbor Estuary, *Washington, Immature growth stages, Migration, Habitats, Estuaries, Growth, Seasonal variation.

Dungeness crabs, Cancer magister, were collected biweekly or monthly from May 1980 to July 1981 in Grays Harbor, Washington. Age of each crab was estimated from width-frequency analyses, and the population density and growth rate were monitored for each age class over the 14-month period. In April 1980 and 1981, crabs entered the estuary either as megalops larvae that metamorphosed to first instar postlarvae or directly as first instars. Intertidal mudflats with beds of eelgrass (Zostera spp.) were important habitats for the first few postlarval stages. Some crabs may have emigrated from the estuary during their second year of life, whereas others dispersed throughout the estuary and appeared to emigrate at sexual maturity (about 2 years). No gravid females were ever found in the bay. Population size was estimated to range from 3.3 million crabs (winter) to 39.0 million crabs (summer); 74% of the summer population were early instars. Growth of early instars was rapid and resulted in a 282-fold increase in dry weight from May to September, but little growth occurred during the remainder of the year. Based on summer population abundance, it is estimated that this estuary could account for a substantial portion of recruitment to the offshore commercial fisheries. (Author's abstract)

s: *Turbulence, *Estuaries, Velocity, ixing, Mathematical equations, Vertical Great Ouse estuary, England.

e measurements of two components of nd of salinity have been made in the e estuary (England) for partially mixed conditions. The data have been used to investigate the dependence on Richardson number of several coefficients associated with the turbulence closure problem. Empirical equations are presented for the variation of the mixing lengths for momentum and solute with Richardson number for the observed conditions. A limited number of evaluations of the turbulence coefficients associated with the flux terms uw (mean) and sw (mean) gave values which were of the same order as those assumed by other workers for neutrally stable conditions. The field measurement techniques have been shown to be feasible and to yield useful results. More measurements are required over a wider range of conditions in order to substantiate these preliminary findings. (Author's abstract)

DISTRIBUTION AND FLUX OF 226RA AND 228RA IN THE AMAZON RIVER ESTUARY,
Princeton Univ., NJ. Geophysical Fluid Dynamics Program.
R. M. Key, R. F. Stallard, W. S. Moore, and J. L. Sarmiento.
Journal of Geophysical Research, Vol. 90, No. C4, p 6995-7004, July, 1985. 6 Fig, 5 Tab, 32 Ref.

Descriptors: *Radium radioisotopes, *Isotope studies, *Amazon River estuary, *Estuarine environment, Suspended particulates, Mixing, Sediments, Geochemistry, Water chemistry.

Measurements of Ra-226 and Ra-228 in the Amazon River estuary show that desorption from river-borne suspended particulate matter in the estuary increases the riverine flux of both isotopes to the ocean by a factor of approximately 5 over the flux attributable to radium dissolved in the river water alone. The total Amazon flux supplies approximately 0.20% of the Ra-226 and approximately 2.6% of the Ra-228 standing crops in the near-surface Atlantic (0-200 m). Diffusive flux from estuarine and shelf sediments and desorption from resuspended sediments in the region of the estuary approximately double the estuarine Ra-226 concentration and quadruple the estuarine Ra-228 concentration above that caused by the dissolved and desorbed river components alone. EXCHANGE OF WATER IN FJORDS: THE EFFLUX/REFLUX THEORY OF ADVECTIVE REACHES SEPARATED BY MIXING ZONES,
National Oceanic and Atmospheric Administration, Seattle, WA. Pacific Marine Environmental Lab.
E. D. Cokelet, and R. J. Stewart.
Journal of Geophysical Research, Vol. 90, No. C4, p 7287-7306, July, 1985. 13 Fig, 1 Tab, 19 Ref.

Descriptors: *Fjords, *Mixing, *Advection, Stratification, Salinity, Saline-freshwater interface, Coastal waters, Path of pollutants.

Many fjords consist of deep, stratified reaches separated by shallower sills above which most of the mixing between water masses occurs. On a long time scale, each reach can be modeled as a steady, two-layer advective flow. These flows intermingle in turbulent mixing zones, where the flow from any incoming layer can be split into two parts: an efflux fraction, which continues on into the next reach, and a reflux fraction, which mixes vertically and recirculates into its original reach. These fractions were defined using conservation of mass, and expressed in terms of the salinities observed in the reaches. The processes of the complex mixing zones need not be considered in detail. These ideas are applicable to complicated branched fjords and linked sequences of reaches. Where more than two reaches meet at a multiple junction the conservation of two tracers (usually fresh water and salt) is insufficient to determine completely the efflux/reflux fractions. We propose an entropy maximization technique to resolve the uncertainty. Long-term pollutant concentrations relate directly to the circulation via the new efflux/reflux formulation. The method demonstrates that refluxing leads to conservative pollutants being broadcast throughout the fjord system with magnified concentrations. A new quantity, the mean tracer age, provides a relevant time scale that includes the effects of recirculation and to which the rates of nonconservative processes should be compared. Conservative pollutants may be retained for a surprisingly long time in a refluxing system. (Author's abstract)

SEDIMENT ACCUMULATION RATES IN IRONDEQUOIT BAY, NEW YORK BASED ON LEAD-210 AND CESIUM-137 GEOCHRONOLOGY,
Geological Survey, San Diego, CA. Water Resources Div.
R. A. Schroeder.
Northeastern Environmental Science, Vol. 4, No. 1, p 23-29, 1985. 4 Fig, 3 Tab, 5 Ref.

Descriptors: *Sedimentation, *Irondequoit Bay, *New York, *Lead radioisotopes, *Cesium radioisotopes, Stratigraphy, Particle size, Erosion, Copper, Zinc, Metals, Estuarine environment.

Recent sediment accumulation rates in Irondequoit Bay, determined by the lead-210 and cesium-137 techniques, range from 0.10 to 0.36 grams per square centimeter per year. The lowest rate is in Ides Cove, a small inlet on the west side of the bay. On the basis of these rates, it is presumed that sediment below a depth of about 1 meter was deposited before European colonization of the basin in the early 1800's. Average flux of lead-210 in the core from Ides Cove, calculated from lead-210 inventories in the core, equals the published atmospheric deposition rate (from measurements in New Haven, Connecticut); but, the average flux of lead-210 is two to three times higher in the cores from the central parts of Irondequoit Bay. The higher flux is most likely caused by preferential scavenging (sediment focusing) on fine-grained sediments. However, direct input of lead-210 attached to eroding material in the watershed is possible. Concentrations of lead, copper and zinc in the sediments show a marked increase beginning about 50 years ago. As in many other areas, this increase is most likely caused by human activities. The increment over natural background levels is a factor of about 14 for lead, 5 for copper, and 4 for zinc. These ratios are much larger than in many water bodies because urbanization covers a comparatively large proportion of this watershed. (Author's abstract)

SHORT-TERM ENDPRODUCTS OF SULFATE REDUCTION IN A SALT MARSH: FORMATION OF ACID VOLATILE SULFIDES, ELEMENTAL SULFUR, AND PYRITE,
Maine Univ., Walpole. Ira C. Darling Center for Research, Teaching and Service.
G. M. King, B. L. Howes, and J. W. H. Dacey.
Geochimica et Cosmochimica Acta, Vol. 49, No. 7, p 1561-1566, July, 1985. 4 Fig, 1 Tab, 39 Ref.

Descriptors: *Sulfate reduction, *Salt marshes, Sulfides, Sulfur, Pyrite, Oxygen, Carbon dioxide, Metabolism, Marshes, Dissolved solids, Volatile compounds, Wetlands.

Rates of sulfate reduction, oxygen uptake and carbon dioxide production in sediments from a short Spartina alterniflora zone of Great Sippewissett Marsh were measured simultaneously during late summer. Surface sediments (0-2 cm) were dominated by aerobic metabolism which accounted for about 45% of the total carbon dioxide production over 0-15 cm. Rates of sulfate reduction agreed well with rates of total carbon dioxide production below 2 cm depth indicating that sulfate reduction was the primary pathway for subsurface carbon metabolism. Sulfate reduction rates

were determined using a radiotracer technique coupled with a chromous chloride digestion and carbon disulfide extraction of the sediment to determine the extent of formation of radiolabelled elemental sulfur and pyrite during short-term (48 hr) incubations. In the surface 10 cm of the marsh sediments investigated, about 50% of the reduced radiosulfur was recovered as dissolved or acid volatile sulfides, 37% as carbon disulfide extractable sulfur, and only about 13% was recovered in a fraction operationally defined as pyrite. Correlations between the extent of sulfate depletion in the marsh sediments and the concentrations of dissolved and acid volatile sulfides supported the results of the radiotracer work. The data suggest that sulfides and elemental sulfur may be major short-term end-products of sulfate reduction in salt marshes. (Author's abstract)

DEVELOPMENT OF A TREED BOG ISLAND IN A MINEROTROPHIC FEN,
Northern Forest Research Centre, Edmonton (Alberta).
S. C. Zoltai, and J. D. Johnson.
Canadian Journal of Botany, Vol. 63, No. 6, p 1076-1085, June, 1985. 5 Fig, 5 Tab, 24 Ref.

Descriptors: *Bogs, *Fens, *Alberta, Vegetation, Nutrients, Calcium, Magnesium, Sulfur, Peat, Trophic level, Trees, Wetlands, Ecology.

Bogs are acid and extremely low in mineral nutrients, while fens are less acidic and more nutrient rich. The development of a heavily treed bog island situated in a wooded fen was studied. The study site itself is a treed bog island, about 0.5 ha in size, situated some 150 m from the edge of a large, 1.2 km wide fen complex in Alberta. An oligotrophic peat layer exists over a mineral-enriched base on the treed island, which supports a predominantly bog vegetation. Macrofossils indicate that the central part of the island has supported oligotrophic treed bog vegetation almost since the beginning of its formation. Three volcanic ash layers allow the reconstruction of the position of the wetland surface at different times. The treed island was initiated on a slight rise and it was always slightly higher than the surrounding fen, maintaining oligotrophic conditions above the fen level. On the treed island, the peat above the fen level is low in such nutrients as calcium, magnesium, and sulfur, but below the fen level the chemical characteristics of the peat are similar to those of the fen peat. Plant remains indicate that conditions have been relatively stable both on the treed island and in the fen; the only major change has been caused by the lateral expansion of the treed island. EFFECT OF SEAWATER MAGNESIUM ON NATURAL FLUORESCENCE DURING ESTUARINE MIXING, AND IMPLICATIONS FOR TRACER APPLICATIONS,
North Carolina Univ. at Wilmington. Div. of Chemistry.
J. D. Willey.
Marine Chemistry, Vol. 15, No. 1, p 19-45, 1984. 10 Fig, 7 Tab, 43 Ref.

Descriptors: *Seawater, *Magnesium, *Fluorescence, *Estuarine environment, *Mixing, *Tracers, Environmental tracers, Humic compounds, Fulvic compounds, Metals, Copper, Iron, Calcium, Salinity.

Natural fluorescence, which is thought to result from low molecular weight humic and fulvic compounds, can be used as a tracer to distinguish between individual river waters. Natural fluorescence exhibits conservative mixing with seawater, except for a slight fluorescence increase which is sometimes observed in the low salinity range (0-5%). This increase is not due to the inner filter effect (internal quenching). Laboratory experiments can reproduce this low-salinity natural fluorescence increase. Of the major seawater ions, only magnesium can cause a similar natural fluorescence increase. Variation in sample pH, ionic strength, or particle content cannot explain the natural fluorescence increase, nor does it appear to be related to the estuarine flocculation of humic material. Addition of seawater magnesium to the fluorescent material with subsequent loss of hydrogen ions could enhance fluorescence by adding crosslinking to the structure. Replacement of a fluorescence-depressing metal like copper or iron by magnesium could also enhance fluorescence, essentially by removing the quenching effect of the metal. Experimental data in this study are consistent with both of these possible mechanisms. Calcium also enhances fluorescence, however the effect of seawater calcium during estuarine mixing is not as apparent as the magnesium effect. The implications of this low-salinity natural fluorescence increase with respect to estuarine and coastal tracer applications depend on whether individual rivers mix in the high or low salinity region of an estuary or coastal area. ORGANIC MATTER IN THE VOLGA DELTA AND DELTA FRONT,
All-Union Research Inst. of Marine Fisheries and Oceanography, Moscow (USSR).
M. P. Maksimova, and M. P. Metreveli.
Water Resources, Vol. 11, No. 4, p 352-360, July-August, 1984. 1 Fig, 2 Tab, 12 Ref. Translated from Vodnye Resursy, No. 4, p 100-109, July-August, 1984.

Descriptors: *Volga Delta, *USSR, *Organic matter, Estuarine environment, Rivers, Chemical compounds, River flow, Seasonal variation, Deltas, Runoff, Caspian Sea.

The concentration and biochemical composition of organic matter in river waters entering the Volga upper delta, delta front, and North Caspian are not identical. The zonal differences are due to the intensity and direction of a number of in situ processes specific for various delta zones. The degree and character of zonal differences of organic matter vary seasonally and also depend on the hydrologic characteristics of the year. Physical processes of erosion of organic matter from soils are most characteristic for the upper zones of the western and eastern parts of the delta, especially in the flood period. Decompositional processes are most pronounced in the lower reach of the delta as a result of a decrease of current speeds. The maximum concentrations of organic matter in delta waters are characteristics for the summer low-flow period; slightly lower concentrations are observed in the fall and the minimum in the winter. In an annual aspect processes leading to enrichment of waters in organic matter dominate in the aggregate of differently directed physical, chemical, and biological processes occurring in the Volga delta and delta front. However, enrichment of river waters of continental runoff inorganic matter in the delta does not lead to an increase of organic runoff to the North Caspian, since a considerable part of the organic matter is deposited in the lower reach. As a result of transformation in the delta, the organic continental runoff undergoes qualitative changes: the organic matter entering the North Caspian is somewhat richer in the nitrogen componen
pared with the organic matter of waters e
the upper delta. (Baker-IVI)

iptors: *Coastal waters, *Legal aspects, h Carolina, Public access, Public rights, En- nental protection, Public trust doctrine, al zone management.

South Carolina Coastal Management Pro- based on the state's 1977 Coastal Zone Man- nt Act articulates ambitious goals and objec- or this valuable zone which includes a 1,241 horeline. Traditionally South Carolina law cognized that the legal boundary between e uplands and adjoining sovereign tidal- l lands is subject to fluctuation as a result of on and erosion, which is consistent with the common-law rule. A provision in the state's management law purports to alter that rule espect to owernship of accreted land. The trust doctrine has not been clearly and ively applied by South Carolina courts, but y cases the courts have indicated that tidal lands are held in trust for the public. South a has historically not encouraged public to the seashore, nor have the state's courts ed coastal access by invoking such legal es as implied dedication and custom, which en used by other jurisdictions. Private land- along South Carolina's coast still enjoy traditional littoral rights, but some con- recently have been imposed under the coastal management law and program. The management program discourages private owners from developing and keeping cer- es of impoundments, such as wetland areas ff from adjacent tidal rivers and estuaries. Carolina's coastal zone leasing activities are ly limited when compared with those of ates, although there are a number of oyster ion and phosphate mining leases. (Baker-

THE COAST IN A CLAMSHELL; I: THE MAINE APPROACH,
P. H. F. Graber.
Shore and Beach, Vol. 52, No. 3, p 17-20, July, 1984. 59 Ref.

Descriptors: *Maine, *Coastal waters, *Legal aspects, Environmental protection, Tidal lands, Public access, Public rights, Public trust doctrine.

As a result of Maine's adherence to the colonial ordinance of 1647, the property boundary between public and private lands within the state's coastal zone is generally the low-water line. The littoral owner of the upland parcel prima facie owns the adjoining tidelands. Maine, like Massachusetts, is among the minority of coastal states in which the low water line generally demarcates public and private ownership in tideflowed lands. Presumably, Maine accepts the traditional common law concepts that property boundaries along the coast change when there is accretion or erosion. Compared with many other coastal states, public access to the shoreline is somewhat restricted in Maine because the vast majority of the tidelands are privately held. Private upland owners in Maine are legally presumed to have the right of access to the ocean along their entire frontage. The director of the state Bureau of Public Lands may lease state-owned tide and submerged lands for statutorily designated purposes, including dredging, filling, or other needs. Submerged lands may be leased for aquaculture or scientific research. A number of statutes regulate activities in the coastal zone. (Baker-IVI)

LAW OF THE COAST IN A CLAMSHELL; PART XVII: THE CONNECTICUT APPROACH,
P. H. F. Graber.
Shore and Beach, Vol. 51, No. 4, p 15-18, October, 1984. 56 Ref.

Descriptors: *Connecticut, *Coastal waters, *Legal aspects, Water management, Environmental protection, Water rights, Public access, Public rights, Public trust doctrine, Planning, Beaches.

Under the Connecticut Coastal Management Program, the state's coastal area stretches seaward to the limit of state jurisdiction in Long Island Sound. The program utilizes a two-tier approach. The first extends only a short distance landward from the shoreline, while the second tier is bounded by the inland limits of 36 coastal municipalities. The high water mark divides the private uplands from the public tidelands. The upland owner is in general entitled to the benefit of gradual accretion to his property. The public trust doctrine has been judicially recognized but apparently not widely applied in Connecticut. Instead, the state has relied on its regulatory authority under the police power to protect public rights. Beaches are a limited resource in Connecticut. Most of the uplands adjoining these beaches are owned by private parties or by beach associations that usually restrict access to the water across their uplands to residents or association members. The right of access to adjoining navigable waters is the fundamental littoral right of upland owners in Connecticut. The state commissioner of agriculture may lease certain areas for the purpose of planting and cultivating shellfish. Although some restrictions on the use of tidal lands and waters had been imposed earlier, Connecticut's most sweeping legislation in this field has occurred during the past quarter century. These regulatory programs reach beyond the control of navigation and encompass environmental and other concerns. (Baker-IVI)

TARAVAL VERTICAL SEA WALL,
San Francisco City, CA.
P. D. Berrigan.
Shore and Beach, Vol. 53, No. 1, p 3-7, January, 1985. 9 Fig, 5 Ref.

Descriptors: *Beaches, *Erosion control, *Seawalls, *California, *San Francisco, Ocean Beach, Erosion, Sediment transport.

There is a serious beach erosion problem at Ocean Beach, San Francisco in the reach between Noriega and Santiago Streets. The problem will not be solved by beach nourishment alone, but can be solved by extending the Taraval Sea Wall to Noriega Street. The Taraval Sea Wall was originally built in 1941 to protect the Great Highway along Ocean Beach. The area is now part of the Golden Gate National Recreation Area, and is also the site of the construction of the Westside Transport, a large sewer for wet weather flow. If the National Park Service will not alter its policy of No Structures on Beaches, it should return to the city the needed strip of duneland which the city donated to the Park Service, in order that the City can have and maintain, at reasonable cost, a proper beach and highway and have control of the area where planting and fences for abatement of blowing sand can be constructed and maintained. LAW OF THE COAST IN A CLAMSHELL; PART XVIII: THE VIRGINIA APPROACH,
P. H. F. Graber.
Shore and Beach, Vol. 53, No.1, p 8-14, January, 1985. 97 Ref.

Descriptors: *Legal aspects, *Virginia, *Coastal waters, Public access, Public rights, Public trust doctrine, Water mangement, Water resources development.

Along Virginia's Atlantic coast, many stretches of the uplands immediately adjoining the shoreline are publicly owned. Under a Virginia statute enacted in 1819, the titles of private landowners of uplands adjoining tidewater were generally extended down to the low water mark. The low water mark as the principal property boundary separating private and public lands, shifts with gradual, imperceptible accretion and erosion. In Virginia, an argument might be made that a provision of the conservation of natural resources, added to the state Constitution in 1971, would support a broader application of this doctrine by the commonwealth's courts. In the 1982 decision involving Hog Island's beaches and marshes the commons concept was favored as a means of protecting public rights. In addition to enjoying the benefit of accretion to their property, private owners of land adjoining tidal waters in Virginia have a number of other rights. The commonwealth's Marine Resources Commission, subject to statutory limitation, is empowered to lease the beds of certain state-owned waters for the prospecting for and removal of oil, gas and other minerals. Coastal zone lands and waters are regulated under three principal statutory schemes: the subaqueous lands management program, the Wetlands Act and the Coastal Primary Sand Dune Protection Act. INLETS AND BARRIER BEACH DYNAMICS: A CASE STUDY OF SHINNECOCK INLET, NEW YORK,
Patchogue, New York.
J. Kassner, and J. A. Black.
Shore and Beach, Vol. 51, No. 2, p 22-26, April, 1983. 5 Fig, 1 Tab, 9 Ref.

Descriptors: *New York, *Shinnecock Inlet, *Beach stabilization, Inlets, Stabilization, Erosion control, Beach erosion, Groins, Sediment transport.

The history of Shinnecock Inlet, its role in coastal processes and the consequences of efforts to stabilize it are reviewed. The dredging and stabilization of the inlet at Shinnecock appear to be the major factors involved in the accelerated erosion of the barrier beach to the west of the inlet. This erosion was exacerbated by the construction of the mid-beach groin field and the failure to backfill the groins to maintain the longshore transport of sediment. This flaw in implementation then led to the construction of additional groins to the west which merely displaced the problem further west. Ironically it appears that the entire beach stabilization project, begun in 1965, may have been unnecessary. By that time, Shinnecock Inlet had entered Period IV and sediment was being naturally by-

passed to the west. The accelerated erosion of the 1950s was therefore significantly reduced. The construction of the groins to address the initial erosion problem caused by the stabilization of the inlet created several others. The history of Shinneock Inlet illustrates the need for comprehensive barrier beach planning and management. Finally, it must be realized that there are no shortcuts in beach stabilization. VISCOELASTIC MODEL FOR INITIAL FLUX DECLINE THROUGH REVERSE OSMOSIS MEMBRANE,
Tohoku Univ., Sendai (Japan). Faculty of Engineering.
Y. Kurokawa, M. Kurashige, and N. Yui.
Desalination, Vol. 52, No. 1, p 9-14, December, 1984. 3 Fig, 10 Ref.

Descriptors: *Reverse osmosis, *Desalination, *Model studies, Flow, Membrane processes, Fluctuations.

Asymmetric cellulose acetate reverse osmosis (RO) membranes exhibit a decline in water flux when operated under RO performance. Especially under the high pressure necessary to desalinate seawater, the membrane creeps and compacts. A homogeneous membrane was prepared from a cellulose acetate butylate (CAB) acetone cast solution. Compression test of the membrane was carried out in such a way that the membrane could be inserted and pressurized mechanically between two cylindrical rods by an electric servohydraulic universal testing machine. RO experiment was performed by using a continuous flow type apparatus. The flux decline through a reverse osmosis membrane is described by assuming that the membrane behaves as a viscoelastic body composed of three elements. This model can be used to predict the flux decline with time for the RO membrane. (Baker-IVI)

EFFECTS OF ACCELERATION ON SPIRAL-WOUND MEMBRANE PERFORMANCE IN REVERSE OSMOSIS,
SRI International, Menlo Park, CA. Engineering Sciences Lab.
J. C. Eid, and G. B. Andeen.
Desalination, Vol. 52, No. 1, p 15-24, December, 1984. 6 Fig, 9 Ref.

Descriptors: *Reverse osmosis, *Desalination, *Buoyance, *Acceleration, Membrane processes, Centrifugation.

Buoyance in reverse osmosis has been considered by several investigators as a means of increasing the flow of contaminants from the membrane surface to reduce fouling and concentration polarization. Buoyance effects arise from the presence of enriched, and thus higher density brine near the membrane, and an acceleration field. An acceleration field placed over a density gradient results in a pressure gradient, which - given proper orientation - leads to a flow. By placing the increasing density gradient in a membrane system in the same direction as the vector of positive acceleration, the flow of contaminants from the membrane surface can be increased. Experimental data show that acceleration, applied to spiral-wound reverse osmosis membranes by centrifugation, increases membrane performance. The effects of acceleration on concentration polarization were determined by testing spiral-wound membranes under accelerations up to 500 x g with 0.5% sodium chloride. The data indicate a reduction in salt concentration at the membrane surface from 2.2 to 1.0% from a nonaccelerated state when 500 x g acceleration is applied to a properly oriented membrane. This reduces the osmotic pressures at the membrane and increases permeate recovery by 21%. (Baker-IVI)

INHIBITION OF CALCIUM SULFATE DEPOSITIONS BY A FLUIDIZED BED,
Akzo Chemie Nederland B.V., Deventer.
J. A. M. Meijer.
Desalination, Vol. 52, No. 1, p 25-42, December, 1984. 15 Fig, 15 Ref.

Descriptors: *Scale, *Fluidized beds, *Desalination, *Calcium sulfate, Seawater, Salts, Temperature effects, Evaporators.

To investigate the influence of the fluidized bed on the deposition of calcium sulfate and to determine the top operational temperature, a test unit with four full-size heat exchanger tubes was built. In these tubes the same mean porosities, the same particles, the same liquid velocities and a comparable heat flux were applied as in an actual multistage flash/fluidized bed evaporator design. Since the attention was mainly focused on the formation of calcium sulfate scale in seawater solutions, the experiments were performed with a brine consisting of calcium, sulfate, magnesium, sodium and chloride ions in water in the same ratio as in standard seawater. In these experiments the top temperature was determined as a function of the following parameters: concentration factor of the brine, exclusion or recirculation of seed crystals, degassing or aeration of the brine, and tube diameter and diameter of the fluidized bed glass particles. In addition, the modification of the deposited calcium sulfate crystals forming the scale layer was examined, as well as the habit of the crystals situated either close to the heat transfer surface or at a certain distance from this surface. In all experiments deposition on the tube walls was prevented as long as the hemihydrate solubility line was not exceeded, yielding a practical procedure to assure scale-free operation of a multi-stage flash/fluidized bed evaporator. The scale layers deposited at temperatures above the hemihydrate line consisted initially of stellated conglomerates of hemihydrate crystals, which frequently seemed to be mixed with substantial amounts of gypsum. This initially formed layer was replaced by an anhydrite layer at a rate enhanced by increasing temperatures and decreasing pH values. (Baker-IVI)

FLOCCULATION, PRECIPITATION, SEDIMENTATION AND FLOTATION FOR USE AS PRETREATMENT STAGES FOR BRACKISH WATER AND SEAWATER IN DESALINATION PLANTS,
Hager und Elsaesser G.m.b.H., Stuttgart (Germany, F.R.).
K. Marquardt.
Desalination, Vol. 52, No. 1, p 43-55, December, 1984. 11 Fig, 3 Ref.

Descriptors: *Pretreatment of water, *Desalination, *Flocculation, *Precipitation, *Sedimentation, *Flotation, Water treatment, Water supply development, Brackish water, Seawater.

Groundwater, bank-filtered river water, brackish water and seawater are increasingly being contaminated by high salt contents and organic, colloidal matter. These different types of water can therefore not be fed to a desalination plant without prior pretreatment. Conventional pretreatment methods are characterized by extensive space requirement, excessive building costs and considerable amount of waste water and sludge which is produced. The objectives of this study were to use precipitation and flocculation reactions for removing inorganic and organic matter; to bring about separation of the suspension by using flotation and sedimentation; to apply these processes in compact units to minimize investment costs; and to include sludge treatment in water processing using mechanical techniques of dehydration. Descriptors: *Mechanical vapor compression process, *Desalination, *Seawater, Evaporation, Water quality, Costs, Drinking water, Industrial water, Water resources development.

The largest mechanical vapor compression process unit for seawater desalination in the world is a 1,500 cu m/d unit installed in the Nuclear Power Plant of Flammanville in France which supplies a high quality water to that plant. The process used in this skid-mounted package unit is distillation: spray-film evaporation working at low temperature (60 C) by mechanical vapor compression (13 C) and multistage process (4 effects). Advantages include: high energy savings; reliability; low temperature; compactness of package units which reduces the transportation and erection costs; simple seawater intake without particular pretreatment; seawater flow 2 times the production flow; high purity of distillate from any kind of seawater; easy operation and maintenance. Such units may be used to produce drinkable water or high purity process water for industrial needs. (Moore-IVI)

DEVELOPMENTS IN VERTICAL TUBE EVAPORATION,
Snamprogetti S.p.A., Milan (Italy). Desalination Dept.
M. Bertuzzi, M. Polla, and P. Tiraboschi.
Desalination, Vol. 52, No. 2, p 135-143, May, 1985.
4 Fig, 3 Tab, 3 Ref.

Descriptors: *Desalination, *Water treatment, *Vertical tube evaporation, Thermodynamics, Multistage flash plants, Snamprogetti process, Evaporation, Salinity, Water resources development.

Multiple effect desalination plants using falling film evaporation and vertical arrangement of the effects have proved significantly advantageous thermodynamically because of reduced energy consumption and advantageous due to high operational flexibilty and due to ease of erection in restricted areas. The combination of a vertical tube evaporation (VTE) plant with an existing multi-stage flash plant is presented with a view to improving its efficiency and production. The VTE plant based on Snamprogetti technology has proved highly reliable as demonstrated by the data relevant to the desalination plant at a refinery; the first unit has been running since March 1978 with a capacity of 1440 cu m/day with an 86% stream factor chiefly caused by shutdowns that occurred due to refinery requirements. The second unit, with a capacity of 2400 cu m/day has been running since October 1982 with a 99% stream factor. Additional utilization of VTE could make the multiple effect technology even more competitive. Desalination plants could be run at a high concentration factor (C.F. $>$ 2) and VTE could be combined with existing multi-stage flash (MSF) units. Operation at higher concentration factors is becoming important as the salinity of seawater has steadily increased along the Arabian Gulf due to the presence of numerous desalination plants. A case study demonstrated the advantages offered by a combined plant; in the case of separate plants the output is equal to that of a combined plant, but the performance ratio is far lower and corresponds to the mean of the MSF performance ratio (8.0 lb/kBtu) and the VTE performance ratio (5.1 lb/lBtu), that is 6.5 lb/kBtu, as compared to 12.3 lb/kBtu of the combined plant. The problem of revamping an existing MSF plant according to the flow diagram presented, can be easily solved from a practical viewpoint, because the installation of a VTE column requires a restricted area. SELECTION OF SMALL DESALINATION PLANTS FOR SPECIFIC LOCATIONS - REVERSE OSMOSIS, FLASH DISTILLATION, VAPOUR COMPRESSION,
Wangnick Consulting Engineers, Gnarrenburg (Germany, F.R.).
K. Wangnick.
Desalination, Vol. 52, No. 2, p 145-165, May, 1985.
29 Fig, 2 Tab.

Descriptors: *Desalination, *Reverse osmosis, *Flash distillation, *Vapor compression, Water treatment, Costs, Economic aspects, Thermodynamics, Decision making, Water resources development.

Selection criteria are given for small desalination plants (2000-3000 cu m/d) for specific locations using reverse osmosis (RO), multistage flash distillation (MSF) or mechanical vapor compression (VC) processes. Of prime economic importance to customers, consultants and manufacturers are peripheral location conditions and operating suitability. Choice by the manufacturers is especially complicated due to the fact that the decision for small plants is left to the bidder. However, based on knowledge of local conditions, manufacturers can anticipate costs. Examples given show that under the assumed conditions the MSF process cannot possibly be the most cost-effective. This applies also to RO when the required product is high-purity process water instead of drinking water. For drinking water any choice between MVC and RO is dependent on energy costs and the capitalization factor. (Author's abstract)

Descriptors: *Desalination, *Economic aspects, *Solar stills, Solar radiation, Energy, Costs, Distillation, Solar distillation, Water treatment, Water resources development.

Since the intensity of solar radiation per unit of evaporating area is determined by nature, the output of a solar distillation unit in a given location can only be increased by increasing the evaporating surface. The productivity of a conventional solar still cannot be more than four to five l/sq m/d for high values of solar radiation. Solar distillation is a free energy operation, however low its efficiency because of low incident radiation. It requires a larger installation area for water production than other conventional desalination processes. Nevertheless it remains the best solution for remote areas and small communities where other water supply systems are not available. Eight solar still designs are illustrated and their physical limitations are discussed. Efficiency of the still plants may be increased by combination with solar collectors, use of available preheated water and by integration with rainwater catchment systems. Solar energy can be converted to thermal, mechanical or electrical energy and then utilized in the solar still process. Solar still efficiency may also be increased by preheating the feed water using condensers inside the solar stills; this method involves additional cost for installation and maintenance and thus may not be justified by the increase in efficiency obtained. It is more economic to install more still units than to attempt to increase the output of a single still by unconventional methods. Distillation with solar energy remains the most favorable process for small capacity water desalting for remote locations where there is considerable solar radiation, but where there are no erection and maintenance facilities or skilled personnel available. In contrast with other desalination processes, in which the cost of energy is very important, if not the major element, solar distillation involves virtually no energy cost. (Collier-IVI)

Group 3A—Saline Water Conversion

5 Fig, 4 Tab, 3 Ref.

Descriptors: *Reverse osmosis, *Desalination, *Distillation, *Multistage flash distillation, Water treatment, Costs, Energy, Environmental effects, Water resources development.

During the last 10 years reversed osmosis (RO) has achieved growing acceptance as an economical and viable alternative to multi-stage flash distillation (MSF) for seawater desalting. The acceptance of this technology is further increasing as a result of plant performance histories and membrane improvements. The abundance of electricity in the Middle East combined with increasing demands for water and restraints on capital spending point to seawater RO as the technology whose time has come. Either alone or in combination with MSF, seawater RO can claim several benefits over MSF: Lower operating costs primarily as the result of energy cost savings. These savings are greater as energy cost increases. Flexibility of operation by the ability to use grid electricity, diversification of plant location and greater load following capability. Replacement of aging MSF plants at minimum capital cost. The ability for power plants to be efficiently designed and operated for power production rather than being controlled by water demands. Combined RO/MSF plants have synergistic benefits through efficiency of plant operation, load following capability, use of excess electricity, product water blending, and lower operating costs than MSF alone. Environmental effects are reduced for a specified quantity of power and water produced due to less fuel burned and warm water discharged to the sea. (Author's abstract)

SEAWATER DESALINATION BY REVERSE OSMOSIS PLANT DESIGN, PERFORMANCE DATA, OPERATION AND MAINTENANCE (TANAJIB, ARABIAN GULF COAST),
Preussag A.G. Bauwesen, Hemmingen (Germany, F.R.). Water Treatment Dept.
W. Heyden.
Desalination, Vol. 52, No. 2, p 187-199, May, 1985. 5 Fig, 5 Tab.

Descriptors: *Desalination, *Reverse osmosis, *Design criteria, *Tanajib, *Saudia Arabia, Water treatment, Seawater, Membrane processes, Water resources development.

A systematic interpretation of critical combinations of feed water, pretreatment and membranes can avoid setbacks in reverse osmosis (RO) processes. RO systems manufacturers will find the right approach if their responsibilities are expanded - beyond just design, construction, installation and commissioning - to an overall responsibility including operation and maintenance. In 1982/83 an oil company ordered a temporary RO seawater desalination plant for Tanajib, on the Arabian Gulf Coast of Saudi Arabia, with a total net capacity of 600,000 gpd. The orders were placed on a turnkey basis including operation and maintenance. The highlights of the RO seawater desalination plant are: shallow beach wells, ultrafiltration, vacuum deaeration, high-pressure multi-stage centrifugal pumps with an energy recovery turbine, single stage reverse osmosis and free programmable logic and process controller. During more than one and a half years of operation, product quantity and quality has always met the design specification. The excellent experience so far with the first temporary Tanajib reverse osmosis seawater desalination plant permit the conclusion that RO technology can avoid setbacks and may face distillation processes competition with confidence. (Author's abstract)

LOW-TEMPERATURE VAPOUR COMPRESSION AND MULTI-EFFECT DISTILLATION OF SEAWATER. EFFECTS OF DESIGN ON OPERATION AND ECONOMICS,
Israel Desalination Engineering Ltd., Tel-Aviv.
R. Matz, and Z. Zimerman.
Desalination, Vol. 52, No. 2, p 201-216, May, 1985. 11 Fig, 3 Tab.

Descriptors: *Distillation, *Vapor compression, *Seawater, *Design criteria, *Economic aspects, Water treatment, Water temperature, Low temperatures, Water resources development.

The design and operating factors are analyzed which lead to the great stability of operation and reliability of low-temperature horizontal tube vapor compression and multi-effect plants. These factors are stated, discussed, and an attempt is made to assess their relative contribution to process economics. Recent reports on the state of the art of desalination technology have indicated the leading position of both low-temperature vapor compression and horizontal tube multi-effect distillation, on technical and economic grounds, for both single- and dual-purpose plants. The practical experience of on-site performance of such has demonstrated the remarkable stability, flexibility and reliability of these processes in comparison with others. The basic concept of low-temperature operation (50-70 C) leads to a chain of interrelated consequences which have a profound effect on the design, economics, operation and maintenance of such plants, some of which can be evaluated in terms of plant and process economics. 3B. Water Yield Improvement

AGRICULTURAL BENEFITS FOR SENEGAL RIVER BASIN,
Army Engineer Battalion (79th), APO New York 09360. Company B.
G. L. Hargreaves, G. H. Hargreaves, and J. P. Riley.
Journal of Irrigation and Drainage Engineering, Vol. 111, No. 2, p 113-124, June, 1985. 4 Tab, 6 Ref, 1 Append.

Descriptors: *Senegal River Basin, *Mauritania, *Mali, *Water resources development, *Agriculture, Economic aspects, Costs, Crops, Computer programs, Irrigation, Water requirements.

A multipurpose water resource development project is proposed for construction and development in the Senegal River Basin. The plans include the irrigation of an area of 274,805 ha by the year 2030 in three countries: Senegal, Mauritania, and Mali. Agricultural benefits were estimated and analyzed by means of a computer program. The factors influencing crop yields were analyzed and summarized including crop selection, water, fertility, and management. Some of the considerations that will produce higher crop yields in future years are presented. It is proposed that the irrigation project management should be responsible for calculating crop water requirements and insuring acceptable irrigation efficiencies. A method is presented for estimating crop water requirements from maximum and minimum air temperatures. The desirability of using irrigation supplemental to rainfall for maximizing benefits from limited water is presented. The maximum contribution of a unit of irrigation water to yield is possible during the rainy season. Projected revenues and costs and years required for each crop to become economically profitable are presented in tables. (Author's abstract)

s in wastewater treatment technology and allow the safe reuse of effluent for sever- es when reasonable precautions are taken. urvey in California indicates that approxi- 20,000 acre-ft (272 million cu m) of er is reclaimed in the state by 240 er plants that supply reclaimed water to n 380 use areas. Irrigation accounts for ately 80% of the total quantity of er reclaimed in the state. Well over half used wastewater in the state is for the of fodder, fiber, and seed crops and for e irrigation of orchards and vineyards - do not require a high degree of er treatment. The Department of Health as established statewide wastewater rec- criteria for various uses, based on the human exposure to pathogens and other nts that could be present in treated r. For most uses of reclaimed water, agents pose a greater health risk than contaminants and quality standards are directed at these agents. The chemical ts are a major concern when reclaimed ed for indirect potable reuse via ground- arge and could also be a concern when water is used for crop irrigation. The contact between irrigation water and the ues of a crop - as influenced by the method practiced - will modify the type nt required for reclaimed water before ural use does not pose a health threat. regulations specify wastewater reuse for irrigation, impoundments and er recharge and include water quality treatment process requirements, sam- analysis requirements, operational re- , and treatment reliability requirements. Water Resources Research, Vol. 21, No. 7, p 927-933, July, 1985. 5 Tab, 9 Ref. Bureau of Reclamation grant 14-34-0001-0477.

Descriptors: *Water conservation, *Rate of return, *Pricing, *California, Municipal water, Utilities, Simulation, Economic aspects.

A significant alternative to physical rationing of water to achieve conservation is provided by the price system. To act like profit maximizing firms, municipal water utilities (MWD's) should price their water so as to earn the opportunity cost of capital (the market rate of return) on the assets. The actual internal rate of return is calculated for a sample of 30 California MWD's for a 12-year period. For the 26 MWD's with a rate of return less than 10%, iterative simulations are run with increases in the MWD's average price to achieve the target rate of return. The magnitude of water conservation using the rate of return rule is reported for three alternative price elasticities of demand. The new implicit prices necessary to achieve the target rate of return are shown to be less than the cost of the cheapest new surface supply. (Author's abstract)

FURROW IRRIGATION SIMULATION TIME REDUCTION,
California Univ., Davis. Dept. of Agricultural Engineering.
M. Rayej, and W. W. Wallender.
Journal of Irrigation and Drainage Engineering, Vol. 111, No. 2, p 134-146, June, 1985. 6 Fig, 15 Ref.

Descriptors: *Furrow irrigation, *Irrigation practices, *Computer models, Model studies, Moving boundary method, Infiltration.

Temporal and spatial changes in the flow profile decrease with time under furrow irrigation, and these slow changes suggest modifications in the simulation methods. Geometrically increasing time steps and node deletion at the upstream boundary are introduced and evaluated for accuracy and CPU time reduction. Increasing the time steps reduced CPU time without sacrificing accuracy significantly in predicting advance. The geometric progression factor is estimated automatically from the first two advance increments, thus incorporating site-specific flow and infiltration characteristics. The moving left boundary method is slightly more accurate, but is less cost-efficient than the varying time-step modification for the example conditions. However, special infiltration conditions may favor the latter method. (Author's abstract)

EFFICIENT WATER USE IN RUN-OF-THE-RIVER IRRIGATION,
Central Luzon State Univ., Munoz (Philippines). Dept. of Agricultural Engineering.
H. L. Angeles, and R. W. Hill.
Journal of Irrigation and Drainage Engineering, Vol. 111, No. 2, p 147-159, June, 1985. 3 Fig, 5 Tab, 10 Ref, 1 Append.

Descriptors: *Irrigation practices, *Water use efficiency, *Philippines, Hydrographs, Model studies, Soybeans, Rice, Drainage, Costs, Seasonal variation.

Irrigation water demand, crop yield and water allocation models were developed and applied to a Philippine run-of-the-river irrigation project. Dry season water supply hydrographs were classified into four levels of availability from high (I) to low (IV). These levels were correlated with the October stream flow volume to provide a prediction of dry season supply. Project net annual benefits could be increased for all four season water supply hydrograph levels by growing an upland crop (soybean) and rice, instead of only rice, providing that costs were less than $90/ha for additional drainage facilities. Net benefits for all rice were greater for reduced area planted, but fully irrigated when the available dry season water supply was lower than average as compared to planting the total area with inadequate irrigation. The irrigation system water demand model was calibrated to match actual diversions for the 1977-78 dry season. The project irrigation efficiency, combined effects of conveyance and application, was determined to be 41%. Thus, a savings in available water supply could be realized by increased system efficiency both from physical modifications as well as from improved management. (Author's abstract)

Journal of Irrigation and Drainage Engineering, Vol. 111, No. 2, p 160-174, June, 1985. 4 Fig, 5 Tab, 17 Ref, 1 Append.

Descriptors: *Water reuse, *Border irrigation, *Irrigation practices, Design criteria, Model studies, Runoff.

Significant and rapid improvement in surface irrigation systems is needed to minimize critical water shortages. There is a great potential for improving surface irrigation systems without affecting the farmer's application method; this can be done with reuse systems. The primary purpose of a reuse system is to collect irrigation runoff water and control it for furthur use. The system requires a sump or reservoir to collect and store the water, pump facilities for pumping it back, and a pipeline or canal for conveying water back to the irrigation system. A procedure is presented for designing a system to reuse runoff from free outflow irrigation borders. Runoff volumes are obtained using four dimensionless variables and runoff curves developed with a zero-inertia mathematical model. The equations make use of runoff curves previously developed to give the components of the reuse system, mainly the sump and pump sizes. Use of

the ultimate post irrigation subsurface water profile was made to get the time of runoff without the need for different design curves. An example of the design procedure includes different modes of reuse system operation. (Collier-IVI)

IMPACT OF RIVER CHANNELIZATION; II. CHANNELIZATION: SOME ENGINEERING ASPECTS,
North West Water Authority, Warrington (England). Rivers Div.
D. L. Hockin.
Geographical Journal, Vol. 151, No. 1, p 54-57, March, 1985.

Descriptors: *Channeling, *Land development, *Flood control, Environmental effects, Design criteria, Drainage, Hydraulic design.

One reason for channelization is to control urban flooding. Land developers have noticed that the floodplain area along a river frequently offers flat land for easy industrial, residential and recreational development, ignoring the fact that this same land is subject to floods during major storms. Other problems which require attention to proper channelization arise from the need to provide improved drainage of agricultural land, and taking care that mining subsidence does not adversely affect natural drainage. Factors which influence channel design and are considered here include hydraulic parameters, the standard of protection that is adopted, adjoining land use, ground conditions, maintenance requirements for channel works, and environmental and amenity aspects. Two of the most frequent criticisms of the engineer's channelization work are indiscriminate removal of trees and vegetative cover from the banks of watercourses and excessive straightening. (Baker-IVI)

IMPACT OF RIVER CHANNELIZATION; III. DOWNSTREAM MORPHOLOGICAL CONSEQUENCES OF RIVER CHANNELIZATION IN ENGLAND AND WALES,
Miljoestyrelsen, Silkeborg (Denmark). Freshwater Lab.
A. Brookes.
Geographical Journal, Vol. 151, No. 1, p 57-62, March, 1985. 3 Fig, 11 Ref.

Descriptors: *Channeling, *England, *Wales, *Environmental effects, *Channelization, Water resources development, Land use, Erosion control, Rivers, Construction, Stream morphology.

Recent field investigations of the downstream morphological consequences of river channelization at a total of 57 water authority sites were reviewed. This research indicates that the downstream consequences can be divided into those effects associated with construction, and characterized by the release of excess amounts of sediment, and those which occur during the years following completion of a scheme in response to changes in the frequency and magnitude of discharges. The majority of sites studied in high energy environments in England and Wales underwent some form of erosive adjustment in the downstream reach in the long term and it is proposed that the increased flows generated by each scheme were sufficient to exceed a threshold required for erosion. Channel enlargement varied spatially, declining with distance away from each channelization scheme. A further type of channel change observed was the accentuated erosion of the outside of bends, but without the associated point bar deposition characteristic of natural landform changes. The majority of sites studied in low energy environments in lowland Britain had not undergone downstream channel change. Analyses of the amount of change produces relationships which can be useful in indicating the amount of adjustment likely in specific situations. (Baker-IVI)

4B. Groundwater Management

GROUNDWATER IN WATER RESOURCES PLANNING: CONJUNCTIVE USE,
Universidad Politecnica de Valencia (Spain).
A. Sahuquillo.
Water International, Vol. 10, No. 2, p 57-63, June, 1985. 25 Ref.

Descriptors: *Groundwater, *Water supply development, *Conjunctive use, Planning, Water management, Water storage, Drought, Water supply.

Growing water needs, the constraints caused by water pollution and the cost of water development projects, including the cost of responding to social and environmental concerns, are increasing dramatically. It has become imperative to take into consideration all water sources and facilities in order to satisfy present and future water demands. Although groundwater has very often been overlooked by planning specialists, it can offer technical and economic advantages worthy of consideration. Groundwater can provide additional resources as well as the means for water storage, distribution and treatment, which can be combined advantageously with surface water resources. Likewise, groundwater can provide other advantages such as its adaptability to a progressive increase in the demand for water, the possibility of temporary overexploitation as a means to defer costly construction projects, mitigate the effects of droughts and alleviate drainage problems. Descriptors: *Irrigation water, *Groundwater management, *Saline waters, *Cropping patterns, Conjunctive use, Water resources, Water quality, Water supply development, Model studies.

A decision model has been developed for optimal cropping pattern based on both leaching requirements and salinity response functions. This model, a deterministic linear programming model, represents the real world situation prevailing in different regions of the world. The model has been a to the command area of a minor canal to t real world problem. The design discharge minor canal is 59 liters/s. The culturable cor area is 28 ha. The full supply days in winter and monsoon season are 131 and 146, respec The command area is irrigated by can groundwater. In order to find the optimal cr pattern and optimal canal and saline groun mix, the possibility of increasing available w mixing canal and saline groundwater in a proportion was examined. The model effe adjusted the cropping pattern according availability of irrigation water as one would in the real world situation. Top priority sho accorded to irrigation extension activities courage conjunctive surface water-groun use. The optimal mixing of surface water an quality groundwater is essential for maximiz returns and to ensure optimum soil conditi plant growth. (Baker-IVI)

ED PROTECTION STRATEGIES SCITUATE RESERVOIR,
nd Dept. of Environmental Manage-idence. Office of Environmental Co-ordination.
L. B. Joubert.
Journal of the New England Water Works Association, Vol. 99, No. 2, p 136-156, June, 1985. 8 Ref.

Descriptors: *Scituate Reservoir, *Rhode Island, *Watershed protection, *Water quality control, Water quality, Drinking water, Water resources development, Non-point pollution sources, Land use, Hazarous materials spills.

The Scituate Reservoir is the sole source of water for the City of Providence and the surrounding metropolitan area. The watershed is predominantly rural in character but it is certainly not isolated. The current study confirmed the excellence of the water quality in the Reservoir. Watershed management and emergency spill response has been effective in maintaining water quality. Contaminants that do find their way into the reservoir from non-point sources and spills have been assimilated and diluted within the system with little effect. Future water quality is subject to increasing traffic volumes and growth pressures - factors over which there is presently little control. Objectives of proposed actions are to improve highway safety and drainge, reduce the amount of hazardous materials transported across the watershed, promote more efficient spill response, and control non-point source discharges through land use management. LIMITS ON THE USEFULNESS OF EROSION-HAZARD RATINGS: EXPERIENCES IN NORTHWESTERN CALIFORNIA,
Pacific Southwest Forest and Range Experiment Station, Arcata, CA.
R. M. Rice, and P. D. Gradek.
Canadian Journal of Forest Research, Vol. 14, No. 4, p 559-564, August, 1984. 1 Fig, 2 Tab, 15 Ref.

Descriptors: *Erosion-hazard ratings, *Logging, *California, Forest management, Soil erosion, Erosion control, Yarding, Prediction.

Although erosion-hazard ratings are often used to guide forest practices, those used in California from 1974-1982 have been inadequate for estimating erosion potential. To improve the erosion-hazard rating procedure, separate estimating equations were used for different situations. The ratings were partitioned according to yarding method, erosional process, and both yarding method and erosional process. Partitioning by yarding method resulted in a slight improvement in the precision of erosion estimates. The other two methods resulted in fourfold increases in prediction errors. Results indicate that a single unified erosion-hazard rating procedure is the most practical way of predicting logging-related erosion in northwestern California. (Author's abstract)

S. N. Nandan, and R. J. Patel.
Polskie Archiwum Hydrobiologii, Vol. 32, No. 1, p 1-6, 1985. 4 Tab, 12 Ref.

Descriptors: *Species diversity, *Algae, *Vishwamitri River, *Baroda, *India, Physico-chemical characteristics, Water pollution, Bioindicators, Indicators, Chemical oxygen demand, Carbonates, Alkalinity, Nitrates, Phosphates, Calcium, Total solids, Water pollution effects.

Shannon's diversity index was studied to analyze the structure of the algal community in the Vishwamitri river flowing through Borada city during December, 1980 to December, 1982. The diversity index was calculated according to Shannon's function. All the three stations selected did not show any difference in the mean values of DI, but the values of each month showed slight variation. The diversity index was correlated with 17 physico-chemical parameters. It showed direct relationships with carbonate, total alkalinity, nitrate, phosphate, calcium and total solids whereas it showed inverse relationships with COD at all 3 stations. DI holds promise as an index for determining the degree of pollution. (Author's abstract)

Based on previously published data on physical and chemical properties of Vistula River water treated for municipal use in the city of Warsaw the processes of mortality, adaptation and reproduction were traced in Paramecium aurelia, P. caudatum and Daphnia magna. In the case of Protozoa, growth parameters of the population were examined (growth rate, generation time) under effect of changes in water chemical properties. It was shown that there is a dependence between water quality as calculated by the method of averaged discriminants, and mortality of test animals. Seasonal and annual changes in mortality of Daphnia magna in the water examined were also ascertained. The organisms used for studies are good bioindicators for the aquatic environment with a high degree of chemical pollution. (Author's abstract)

METAL CONCENTRATIONS IN THE GROUND WATER OF THE OUCHITA MOUNTAINS, ARKANSAS, U.S.A.,
Arkansas Univ., Fayetteville. Dept. of Geology.
G. H. Wagner, and K. F. Steele.

Water, Air, and Soil Pollution, Vol. 25, No. 3, p 339-347, July, 1985. 2 Fig, 2 Tab, 18 Ref.

Descriptors: *Groundwater, *Metals, *Ouachita Mountains, *Arkansas, Manganese, Drinking water, Water quality, Lead, Iron, Zinc, Cadmium, Copper, Cobalt, Nickel, Mercury, Antimony, Strontium, Barium.

Groundwater in the Ouachita Mountains near deposits of Mn-oxide mineral deposits have anomalously high Mn and Fe concentrations in a significant percentage of cases (Mn-50%, Fe-44%) and background concentrations of Mn and Fe for these groundwaters tend to be greater than for lesser mineralized areas. There is some evidence that the trace metals in these Mn mineral deposits also are reflected in greater groundwater concentrations. Barite and cinnabar mineral deposits are similarly reflected in higher concentrations of Ba and Hg, respectively, not only in the groundwater near these deposits, but also generally in the mineralized districts. The concentrations of Mn and Fe in about 30% of the springs exceeded the EPA drinking water criteria of 50 micro-g/L Mn and 300 micro-g/L Fe. Three springs exceeded the EPA criterion for Pb of 50 micro-g/L, one spring exceeded the 2 micro-g/L Hg criterion and no Ba concentrations exceeded the Ba criterion of 1000 micro-g/L. (Baker-IVI)

DETERMINATION OF ALKYLPHENOLS AND ALKYLPHENOL MONO- AND DIETHOXYLATES IN ENVIRONMENTAL SAMPLES BY HIGH-PERFORMANCE LIQUID CHROMATOGRAPHY,
Eidgenoessische Anstalt fuer Wasserversorgung, Abwasserreinigung und Gewaesserschultz, Duebendorf (Switzerland).
M. Ahel, and W. Giger.
Analytical Chemistry, Vol. 57, No. 8, p 1577-1583, July, 1985. 4 Fig, 4 Tab, 19 Ref.

Descriptors: *Pollutant identification, *Alkylphenols, Chromatography, Organic compounds, Wastewater analysis, Water analysis, High-performance liquid chromatography, Mass spectrometry, Gas chromatography.

Rapid, reliable and sensitive methods for the quantitative determination of alkylphenols (AP), 4-alkylphenol mono- (AP1EO) and diethoxylates (AP2EO) in wastewaters, natural waters, and sludges were sought. The necessary prerequisites for successful quantitative determinations of chemicals in environmental research are efficient and preferably selective enrichment, effective separation, and specific and sensitive detection. For routine determinations of large numbers of samples, simplicity and ease of operation as well as short analysis times are desirable. The normal-phase high-performance liquid chromatography (HPLC) method for the quantitative determination of 4-nonylphenol, 4-nonylphenol mono- and diethoxylate described largely fulfills these requirements. High-resolution gas chromatography/mass spectrometry and reversed-phase HPLC may serve as confirmatory techniques to ensure correct identifications. A broad range of aqueous and solid samples from different processes of wastewater and sludge treatment and from various compartments of the environment can be analyzed. The method is particularly suitable for investigations of the occurrence and fate of AP, AP1EO and AP1EO in sewage sludges, treated wastewaters and in the aquatic environment. (Baker-IVI)

Malaga Univ. (Spain). Dept. de Ecologia.
P. Algarra, and F. X. Niell.
Investigacion Pesquera, Vol. 49, No. 1, p 107-119, 1985. 6 Fig, 1 Tab, 24 Ref.

Descriptors: *Chlorophyll a, *Marine environment, Water pollution effects, Probability, Pigments.

The Whitney and Darley's method to estimate chlorophyll a free of degradation products, has been compared with the classical method of Talling and Driver which does not discriminate these interferences. Both methods have been used to estimate gradiental changes in three sytems stressed by a single or a double focus. The amount of impact, as a percent, has been estimated by means of a probabilistic method based on Montecarlo methodology using as variable the values of active chlorophyll a. The general discussion of the data suggest problems of theoretical interest. (Author's abstract)

SIMPLE, COMMUNITY LEVEL, ECOTOXICOLOGICAL TEST SYSTEM USING SAMPLES OF PERIPHYTON,
Goeteborg Univ. (Sweden). Dept. of Botany.
H. Blanck.
Hydrobiologia, Vol. 124, No. 3, p 251-261, May, 1985. 8 Fig, 4 Tab, 59 Ref.

Descriptors: *Periphyton, *Photosynthesis, *Phytotoxicity, Water pollution effects, Algae, Ecotoxicity, Aliphatic amines, Industrial wastewater, Textile industry.

The design and performance of a simple, community level ecotoxicological test system is reported. Samples of periphyton communities, established on artificial substratum in natural streams were used to study effects on photosynthetic activity in short-term experiments. Photosynthesis was measured as light-dependent oxygen evolution or as C-14 labeled CO2-incorporation. The variability in photosynthetic activity between samples collected at the same time, expressed as coefficient of variation, was ca. 20%. The variation in sensitivity of periphyton photosynthesis as dependent on sampling season was less than threefold for the two long-chained aliphatic amines and the textile industry effluent studied. Effects of the amines on periphyton from five different streams were also investigated. The ratio between maximum and minimum values of sensitivity was 5.6. It is concluded that the variation in sensitivity between different periphyton communities is similar to or less than that observed for fresh-water algal species. Some advantages with regard to ecological realism of using periphyton communities as test systems are discussed. (Author's abstract)

QUANTITATIVE CHEMOBEHAVIOR OF FISH: AN IMPROVED METHODOLOGY,
Texas A and M Univ., College Station. Dept. of Veterinary Anatomy.
A. D. Scarfe, C. W. Steel, and G. K. Rieke.
Environmental Biology of Fishes, Vol. 13, No. 3, p 183-194, July, 1985. 7 Fig, 27 Ref.

Descriptors: *Fish behavior, *Monitoring, *Octagonal fluvarium, Behavior, Water pollution, Odor, Chemobehavior, Food habits.

A new behavioral monitoring system, an 'octagonal fluviarium', and associated time-series analytical techniques were developed to quantitatively examine and assess the chemobehavior of fish to waterborne chemicals. Together they aid in the solution of many of the quantitative behav physical problems inherent in earlier exp approaches. The fluviarium utilizes a quas channel in which fish are able to mo through any of eight areas, any of w/ receive a predetermined concentration of cal stimulus. Movements and preferential animals monitored with a video system lyzed to determine spatial and temporal p in their distributions within the system in to introduced chemicals. The advantages designs include precise control of the w dynamics affecting the odor plume, virtua tion of the 'wall-hugging' tendency of an to the quasi-circular construction of the trough, and the assessment of temporal c the behavioral responses of the animals w be correlated with the presence of od cues. The efficacy of the fluviarium and analysis is illustrated with data on the sponse of zebrafish, Brachydanio rerio, to L-alanine. This system should have extens cation in investing the chemoresponses o organisms to waterborne chemicals (pres gularly and in combinations) such as f stances, pheromones or pollutants. (Aut stract)

POLYCHLORINATED BIPHENYLS HUDSON RIVER: THE VALUE OF UAL PACKED-COLUMN PEAK ANAL
Lamont-Doherty Geological Observat sades, NY.
H. J. Simpson, R. F. Bopp, B. L. Deck, S and N. Kostyk.
Northeastern Environmental Science, V 3/4, p 159-165. 10 Fig, 6 Tab, 14 Ref.

Descriptors: *Polychlorinated biphenyls, River, *New York, *Packed-column pea

ical analysis, *Fate of pollutants, Chlorinat-drocarbons, Sediments, Chemical composi-

result of discharges of approximately 500 PCBs since the 1940's, the sediments, water ta of the Hudson River (New York) over a reach are contaminated to a level up to orders of magnitude greater than other rban river-estuaries in North America. Al- the original contamination probably con- predominantly of unmodified commercial ixtures, especially Aroclor 1242 which was about 80 km upstream of tidal waters, the ive effect of physical and biological proc- ncluding sorption and desorption to and spended particles and sediments plus gas e between the water and atmosphere, has accomplish major changes in PCB compo- nposition in sediments along the axis of the dson. Much of the scientific value of envi- al PCB measurements in the Hudson is lost rting of data as total PCB concentrations, an in terms of a number of distinct compo- leally, each of the more than 100 individual ngeners that can be analyzed in environ- amples by capillary column chromatogra- uld be separately reported, but in practice cant advance would be accomplished by g data in terms of mass of PCB represen- individual peaks resolved by packed- chromatography (each peak includes sev- nct compounds with very similar physio- properties). Less informative, but never of considerable value, is the practice of data in terms of one or more commercial mixtures, especially if the method of zation is carefully documented (i.e. which gram peaks are actually used for both the and sample). Comparison of PCB compo- ased on individual packed-column peak n depth segments of a sediment core from upstream end of the tidal Hudson demon- at even relatively subtle changes in PCB mposition (conversion from Aroclor 1242 r 1016), such as occurred at the upstream cilities in 1971-1972, can be clearly ob- the sediments many 10's of km down- f the release points, providing a useful hic marker. In contrast to such subtle n PCB source composition to the tidal er Hudson, major differences are ob- sediment PCB composition near New . In an area such as Jamaica Bay, which isolated from the influence of down- nsport of PCBs from the capacitor plant ediment PCBs contain much greater pro- f higher chlorinated biphenyls (penta- biphenyls) than the main stem of the probably due to the impact of domestic scharges. Such large difference in com- rovide the single most useful set of infor- r characterizing sources and transport of this family ot toxic contaminants in n. (Author's abstract)

ORGANISMS AS INDICATORS OF QUALITY IN LAKE PATZCUARO,
Universidad Nacional Autonoma de Mexico, Mexico City. Dept. de Quimica de la Atmosfera y Estudios del Agua.
I. Rosas, M. Mazari, J. Saavedra, and A. P. Baez.
Water, Air, and Soil Pollution, Vol. 25, No. 4, p 401-414, August, 1985. 8 Fig, 3 Tab, 34 Ref.

Descriptors: *Lake Patzcuaro, *Mexico, *Benthos, *Water quality, *Bioindicators, Water pollution effects, Bacterial analysis, Animal wastes, Invertebrates, Aquatic plants, Wastewater pollution.

The water quality was evaluated in Lake Patzcuaro by biological methods using bacteria and macroinvertebrates as indicators, as well as physicochemical parameters. The bacteriological determinations showed critical areas near the two main villages, Patzcuaro and Janitzio. The bacterial ratio FC/FS indicated significant amounts of animal excreta throughout the lake. In areas with less urban influence where there was an abundance of immersed vegetation, the benthic macroinvertebrate community presented high Bioic, Diversity, and Equitability Indices, which were > 2, > 2, and > 0.6, respectively. At the most polluted station (station 8), oligochaetes, which are tolerant to organic matter, comprised 94% of the organisms. Physicochemical characteristics are similar in the lake, except at station 8 where the lowest dissolved oxygen levels, highest ammonia and phosphorus concentrations were registered. This area, adjacent to a fish processing plant, is affected by domestic and industrial wastewater discharges. The results show that up to the present the lake has been moderately polluted, but critical zones exist that restrict the use of the lake for water supply and recreational purposes. USE OF IONIC MIXING CURVES IN DIFFERENTIATING OIL FIELD BRINE FROM NATURAL BRINE IN A FRESH WATER AQUIFER,
Oklahoma State Univ., Stillwater. Dept. of Civil Engineering.
V. A. Mast.
Ground Water Monitoring Review, Vol. 5, No. 3, p 65-69, Summer, 1985. 5 Fig, 2 Tab, 4 Ref.

Descriptors: *Pollutant identification, *Brines, *Saline water intrusion, Dissolved solids, Chlorides, Statistical studies, Model studies, Water pollution sources.

The study and analytical technique used to determine the relative contribution of various pollution sources to the increased salinity of the fresh water aquifer in the south Wichita, Kansas area were investigated. A statistical model is presented which has proven to be a valuable tool in determining the percentage contribution of pollution from the various sources of contaminants. For the most reliable factors, chloride and total dissolved solids, the volumetric percentage contribution of oil field brine and Wellington Formation natural brine at the bottom of the aquifer ranged from 6.5% to 8.5% and 6.8% to 7.1%, respectively. For the analytical model itself, two drawbacks are pointed out. First, the water system in the model is highly simplified. For a system with more than two potential pollutant sources, this analysis will not serve a proper function. Second, the choice of factor pairs is site dependent. With different geological environments, as well as different pollutant types, the factor pairs used must be chosen accordingly. Three suggestions are made for future analysis in multisource pollution systems: for the unsteady-state system, a time factor should be included in the analysis; for a system of N number of pollutant sources, factor group of N items should be used for analysis; and every item in the factor group selected should represent the characteristics of the respective pollutant sources. GROUND WATER QUALITY ANOMALIES ENCOUNTERED DURING WELL CONSTRUCTION, SAMPLING AND ANALYSIS IN THE ENVIRONS OF A HAZARDOUS WASTE MANAGEMENT FACILITY,
Woodward-Clyde Consultants, Walnut Creek, CA. Environmental and Engineering Services.
D. Dunbar, H. Tuchfeld, R. Siegel, and R. Sterbentz.
Ground Water Monitoring Review, Vol. 5, No. 3, p 70-74, Summer, 1985. 1 Fig, 3 Tab, 1 Ref.

Descriptors: *Water quality, *Monitoring, *Well construction, Construction, Wells, Hazardous waste, Hydrogeology, Waste disposal, Aquifer characteristics, Potentiometry, Tetrahydrofuran, Trihalomethanes, Organic compounds, Water pollution sources.

The occurrence of a number of ground water quality anomalies during field investigations demonstrates the need for careful attention to specialized well construction, sampling and analytical procedures. The specific anomalies and their corresponding causes include elevated pH values due to poor well construction procedures; the presence of tetrahydrofuran, caused by the use of glue at casing joints; the temporary occurrence of trihalomethanes produced during the breakdown of synthetic drilling fluid; and cross contamination of groundwater samples due to incomplete equipment decontamination procedures. REDUCTION OF HEXAVALENT CHROMIUM IN WATER SAMPLES ACIDIFIED FOR PRESERVATION,
Geological Survey, Denver, CO.
K. G. Stollenwerk, and D. B. Grove.
Journal of Environmental Quality, Vol. 14, No. 3, p 396-399, 1985. 3 Fig, 1 Tab, 19 Ref.

Descriptors: *Chromium, *Sample preservation, *Hexavalent chromium, Water chemistry, Preservation, Chemical reactions, Hydrogen ion concentration, Nitrates, Organic carbon, Water temperature.

Reduction of hexavalent chromium, Cr(VI), in water samples, preserved by standard techniques, was investigated. The standard preservation technique for water samples that are to be analyzed for Cr(VI) consists of filtration through a 0.45-micro-m membrane, acidification to a pH < 2, and storage in plastic bottles. Batch experiments were conducted to evaluate the effect of H(+) concentration, NO2, temperature, and dissolved organic carbon (DOC) on the reduction of Cr(VI) to CR(III). The rate of reduction of Cr(VI) to Cr(III) increased with increasing NO2, DOC, H(+), and temperature. Reduction of Cr(VI) by organic matter occurred in some samples even though the samples were unacidified. Reduction of Cr(VI) is inhibited to an extent by storing the sample at 4 C. Stability of Cr(VI) in water is variable and depends on the other constituents present in the sample. Water samples collected for the determination of Cr(VI) should be filtered (0.45-micro-m membrane), refrigerated, and analyzed as quickly as possible. Water samples should not be acidified. Measurement of total Cr in addition to Cr(VI) can serve as a check for Cr(VI) reduction. If total Cr is greater than Cr(VI), the possibility that Cr(VI) reduction has occurred needs to be considered. (Author's abstract)

ESTIMATING ALGAL AVAILABLE PHOSPHORUS IN SUSPENDED SEDIMENTS BY CHEMICAL EXTRACTION,
Purdue Univ., Lafayette, IN. Dept. of Agronomy.
R. A. Dorich, D. W. Nelson, and L. E. Sommers.
Journal of Environmental Quality, Vol. 14, No. 3, p 400-405, 1985. 1 Fig, 3 Tab, 31 Ref.

Descriptors: *Phosphorus, *Algae, *Suspended sediments, *Chemical analysis, *Extraction, Sediments, Bioavailability, Nutrients, Cycling nutrients.

The availability of sediment inorganic phosphorus (P sub i) to algae was determined in 28 suspended stream sediments collected from an agricultural watershed in northeastern Indiana by short (2-d) and longer-term (14-d) incubations. Unincubated sediment was also analyzed for dissolved molybdate reactive P sub i (DMRP) and P sub i extracted by: (i) sequential NaOH and HCl, (ii) sequential NH4F, NaOH, and HCl, (iii) nitrilotriacetic acid (NTA), (iv) hydroxy-Al resin, and (v) total P. Available P (P sub aa) measured in sediments by 2-d and 14-d incubations with algae averaged 21 and 25% of total sediment P, respectively. Extraction of sediments with 0.1 M NaOH, 0.5 M NH4F, sequential 0.5 M NH4F + 0.1 M NaOH, NTA, and hydroxy-Al resin removed an average of 36, 22, 31, 45, and 17% of the total P, respectively. Of the extractants tested, NaHO-extractable P sub i was significantly correlated with 2-d and 14-d P sub aa ($r = 0.89^{***}$ and 0.95^{***}, respectively) but NaOH extraction removed amounts of P sub i that exceeded sediment P sub aa by a relatively constant amount. The results suggest that a single extraction with 0.1 M NaOH can be used to estimate both short- and longer-term P sub aa in suspended stream sediments derived from noncalcareous soils in the Northcentral USA. DETERMINATION OF POTASSIUM, SODIUM, CALCIUM, AND MAGNESIUM IN NATURAL WATERS BY ION CHROMATOGRAPHY,
Iowa State Univ., Ames. Dept. of Agronomy.
N. T. Basta, and M. A. Tabatabai.
Journal of Environmental Quality, Vol. 14, No. 3, p 450-455, 1985. 4 Fig, 5 Tab, 20 Ref.

Descriptors: *Potassium, *Sodium, *Calcium, *Magnesium, *Chemical analysis, *Ion chromatography, Chromatography, Conductimetric detection, Metals, Iron.

Simultaneous determination of alkali and alkaline earth metals in water samples is needed. Studies to evaluate the Dionex Model 10 Ion Chromatograph (IC) for simultaneous determination of K and Na or Ca and Mg in diverse types of natural waters, including soil extracts, showed that the results by the IC method closely agreed with those obtained by flame photometry for K and Na and by atomic absorption spectrophotometry of K, Na, Ca, and Mg. The IC method is based on separation of the monovalent and divalent cations by a separator column containing a low-capacity sulfonated divinylbenzene polystyrene copolymer, cation-exchange resin in the H(+) form and on converting the various metal ions to their corresponding hydroxides by a suppressor column containing a high-capacity, anion-exchanged resin in the OH(-) form. The eluent used for determination of alkali metals was 5 mM HCl, and a solution containing 2.5 mM HCl + 2.5 mM m-phenylenediamine dihydrochloride was used for determination of alkaline earth metals. Electrical conductivity is used as the mode of detection. The method is precise, accurate, and can detect as little as 0.1 mg/L of K, Na, Ca, or Mg in water samples. The coefficient of variation values ranged from 1.3 to 5.0% for K, from 0.63 to 9.1% for Na, from 1.9 to 3.5% for Ca, and from 0 to 24% for Mg. With the IC method, K and Na or Ca and Mg can be determined simultaneously in 2 mL of water in approximately 7 min. A single operator can perform about 40 analyses of alkali or alkaline earth metals in a normal working day. Successive analyses of waters containing high concentrations of metals (e.g., Fe) may lead to loss of resolution of alkali metals, but this can be restored by washing the separator column with 3 M HCl saturated with EDTA. (Author's abstract)
W86-01717

PRECONCENTRATION AND X-RAY SPECTROMETRIC DETERMINATION OF ARSENIC(III/V) AND CHROMIUM(III/VI) IN WATER,
Link Systems Ltd., High Wycombe (England).
D. E. Leyden, K. Goldbach, and A. T. Ellis.
Analytica Chimica Acta, Vol. 171, p 369-374, 1985. 2 Fig, 4 Tab, 5 Ref.

Descriptors: *Pollutant identification, *Spectrometry, *Arsenic, *Chromium, Water analysis, Chemical analysis, Speciation.

Two precipitation methods have been used successfully to determine chromium and arsenic in their respective oxidation states in water samples. The DBDTC (dibenzyldithiocarbamate) precipitation method recovers Cr(VI) and As(III) selectively over Cr(III) and As(V) as a first precipitation step. The remaining Cr(III) and As(V) are quantified in a second step by coprecipitation with hydrated iron(III) oxide. Sensitivity is higher for chromium and arsenic by the DBDTC method because of increased matrix absorption for iron(III) in the coprecipitated samples. The method will likely not supplant atomic absorption or inductively coupled plasma emission spectrometry for accuracy and precision, but it does provide speciation information and a fast economical method. Standards can be stored indefinitely. (Baker-IV)

ZIRCONIUM COPRECIPITATION FOR SIMULTANEOUS MULTIELEMENT DETERMINATION OF TRACE METALS IN SEAWATER BY INDUCTIVELY COUPLED PLASMA ATOMIC EMISSION SPECTROMETRY,
Tokyo Univ. (Japan). Dept. of Chemistry.
T. Akagi, Y. Nojiri, M. Matsui, and H. Haraguchi.
Applied Spectroscopy, Vol. 39, No. 4, p 662-667, 1985. 3 Fig, 5 Tab, 38 Ref.

Descriptors: *Zirconium, *Coprecipitation, *Precipitation, *Chemical analysis, *Seawater, *Inductively Coupled Plasma Atomic Emission Spectrometry, *Trace metals, Metals, Preconcentration, Spectroscopy, Atomic emission spectrometry, Inductively coupled plasma.

Zirconium coprecipitation for simultaneous multielement determination of trace metals in seawater has been examined by inductively coupled plasma atomic emission spectrometry. Optimum pH conditions and other experimental procedures for coprecipitation were investigated in order that the method for multielement preconcentration could be evaluated. The concentration factor of 20 times the original concentration was obtained, although it was limited by spectral interference with zirconium. The present coprecipitation method improved the detection limits and other analytical figures of merit for 17 trace metals (Al, As, Cd, Co, Cr, Cu, Fe, La, Mn, Mo, Ni, Pb, Sb, Ti, V, Y, and Zn), which were estimated by the use of artificial seawater samples, and it was applied to natural seawater analysis. ATION OF NONIONIC SURFAC-
VATER BY ATOMIC ABSORPTION
ETRY,
Waterwerken (Belgium).
oof, W. J. Van Craenenbroeck, and J.

International Journal of Environmental Analytical Chemistry, Vol. 19, p 155-164, 1985. 2 Fig, 1 Tab, 11 Ref.

Descriptors: *Surfactants, *Atomic absorption spectrometry, Sublation, Ion exchange, Pollutant identification, River Meuse, France, Belgium, Netherlands.

An analytical method for nonionic surfactants has been developed using sublation and ion-exchange for isolation of the surfactants and complex formation with potassium zinc tetrathiocyanate followed by atomic absorption spectrophotometric assay of zinc released from the complex through acid extraction. The detection limit for this method is 0.01 mg/l Triton X-100. Recoveries higher than 90% were obtained starting from samples spiked with 0.1 mg/l Triton X-100. The method has been applied to 70 surface water samples coming from a quality survey of the River Meuse in France, Belgium and The Netherlands organized by the RIWA-Cooperating Rhine and Meuse Water Supply Companies. The highest level (0.50 mg/l) was found below the outfall of a surfactant-producing firm. Downstream these discharge levels decreased rapidly. (Author's abstract)

VARIABILITY OF ALUMINUM CONCENTRATIONS IN ORGANS AND WHOLE BODIES OF SMALLMOUTH BASS (MICROPTERUS DOLOMIEUI),
Columbia National Fisheries Research Lab., MO.
W. G. Brumbaugh, and D. A. Kane.
Environmental Science and Technology, Vol. 19, No. 9, p 828-831, 1985. 6 Tab, 20 Ref.

Descriptors: *Aluminum, *Bass, Metals, Pollutant identification, *Fish, Atomic absorption spectrophotometry, Gills, Water pollution effects, Animal tissues.

Variability of aluminum concentrations in smallmouth bass (Micropterus dolomieui) was evaluated by analysis with graphite furnace atomic absorption spectrophotometry. Fish analyzed as whole bodies were compared to fish which had selected organs analyzed individually and separately from the carcass. Gastrointestinal tract contents contained highly variable amounts of aluminum and caused bias and increased variability when included in whole-body samples. Since aluminum concentrations in tissues of stomach and intestine were similar to those in the whole body (less gastrointestinal tract contents), the entire gastrointestinal tract and contents could be removed to reduce bias and variability without measurably altering the 'true' whole-body aluminum concentrations. Of the organs analyzed, gill filaments had the highest and most variable aluminum concentrations and may have contributed to within-fish whole-body variability because of incomplete homogenization. FRESHWATER AQUATIC MACROPHYTES AS HEAVY METAL MONITORS - THE OTTAWA RIVER EXPERIENCE,
National Research Council of Canada, Ottawa (Ontario). Div. of Biological Sciences.
D. C. Mortimer.
Environmental Monitoring and Assessment, Vol. 5, No. 3, p 311-323, September, 1985. 2 Fig, 7 Tab, 15 Ref.

Descriptors: *Macrophytes, *Heavy metals, Monitoring, Seasonal variation, Plant growth, Lead, Mercury, Nickel, Copper, Aquatic plants, Ottawa River.

The ability of freshwater aquatic vascular plants to accumulate heavy metals was examined in some detail during a five year study. Differences in uptake rate were found to depend on the species of plant, the seasonal growth rate changes and the metal ion being absorbed. Lead and mercury were concentrated to a greater extent than the lighter nickel and copper. Laboratory experiments were designed to establish uptake rate constants which were used to calculate water concentrations of mercury from the analyses of plant samples from the river. 'Background' levels of mercury in aquatic plants of 35-50 ng/L dry weight corresponded to a water concentration near 15 ng/L of total mercury of which 25-30% was methyl-mercury. Higher concentrations of mercury in the plants indicated a proportional increase in the mercury level in the water. (Author's abstract)

AVOIDANCE TEST OF A FISH, MEDAKA (ORYZIAS LATIPES), TO AQUATIC CONTAMINANTS, WITH SPECIAL REFERENCE TO MONOCHLORAMINE,
Ehime Univ., Matsuyama (Japan). Dept. of Environment Conservation.
H. Hidaka, and R. Tatsukawa.
Archives of Environmental Contamination and Toxicology, Vol. 14, No. 5, p 565-571, September, 1985. 4 Fig, 1 Tab, 22 Ref.

Descriptors: *Fish behavior, *Monochloramine, *Avoidance, Medaka, Bioindicators, Toxicity, Chlorine, Surfactants, Residual chlorine, Chloramines, Water pollution effects.

The avoidance behavior of fish is a sensitive indicator for aquatic contaminants such as surfactants, pesticides, and residual chlorine. A monochloramine avoidance test was carried out using medaka (Oryzias latipes) in a small modular chamber system with a symmetrical parallel-flow. In the apparatus, the diluted toxicant solution and the control water run parallel with a distinct boundary at the center of the chamber. The significant avoidance concentration (P = 0.05) was 5.7 micro-g/L as combined residual chlorine, which is the lowest residual chlorine avoidance concentration reported in the literature. The avoidance curves for monochloramine exhibited a pattern similar to those for anionic surfactants. As the avoidance behavior of fish is a sensitive indicator, this avoidance test may be used as one of the standard methods for ecotoxicological studies. (Moore-IVI)

COLORIMETRIC DETERMINATION OF PROPOXUR RESIDUES IN VEGETABLES AND WATER,
Central Food Technological Research Inst., Mysore (India). Analytical Quality Control Lab.
K. M. Appaiah, M. A. Sreenivasa, and O. P. Kapur.
Bulletin of Environmental Contamination and Toxicology, Vol. 296-300, September, 1985. 2 Tab, 17 Ref.

Descriptors: *Propoxur, *Insecticides, *Colorimetry, India, Pollutant identification, Water analysis, Pesticide residues.

Propoxur is a non-systemic insecticide used on a large scale in India on field crops. Although gas and liquid chromatographic methods are ideal for detecting and quantifying propoxur residues their use is often limited by availability and cost of equipment. The advantages of the colorimetric method proposed are that it does not require elaborate clean-up technique, gives high recovery, produces a stable color and is as sensitive as the method which uses 4,4-diaminodiphenyl sulfone as the chromogenic reagent. The phenol obtained after alkaline hydrolysis of propoxur is treated with concentrated nitric and sulfuric acids to get nitrosophenol which is in the presence of excess of alcoholic ammonium hydroxide rearranges to form a highly colored quinoid salt. The color is stable for weeks. To check the adequacy of the method, water and vegetable samples were fortified with known amounts of propoxur and analyzed. Recov-

eries ranged from 95.1 to 98.0% for water samples, and 93.5 to 97.8% for vegetable samples. (Baker-IVI)

DAPHNIA MAGNA AS AN INDICATOR OF THE ACUTE TOXICITY OF WASTE WATERS,
National Board of Waters, Helsinki (Finland). Water Research Inst.
E. Nikunen, and V. Miettinen.
Bulletin of Environmental Contamination and Toxicology, Vol. 35, No. 3, p 368-374, September, 1985. 1 Tab, 21 Ref.

Descriptors: *Daphnia, *Toxicity, *Wastewater disposal, *Water pollution effects, *Bioindicators, Indicators, Zooplankton, Pulp wastes, Pulp and paper industry, Industrial wastewater.

The proposed Finnish standard for both chemical and wastewater testing is described and results obtained with different industrial wastewaters using the test method are presented. The wastewater samples taken for the experiments were mainly chosen by the local water authorities. The majority of the tested effluents were taken form the pulp and paper industry, which is the most important polluter of the Finnish waters. The tests conducted on Daphnia magna indicated that the proposed Finnish standard is a fairly rapid and easy method for measuring the acute lethal toxicity of waste water samples. Pulp and paper mills had clearly the biggest toxicity emission rates of the samples investigated. Just one other plant, producing viscose fibers, had a TER (toxicity emission rate) value which was in the same order of magnitude as the median values of wastewaters released from different pulp producing plants. MONITORING OF POLYCHLORINATED BIPHENYLS (PCBS) AND HEXCHLOROCYCLOHEXANES (HCH) IN FRESHWATER USING THE AQUATIC MOSS CINCLIDOTUS DANUBICUS,
Metz Univ. (France). Lab. d'Ecologie.
C. Mouvet, M. Galoux, and A. Bernes.
Science of the Total Environment, Vol. 44, p 253-267, 1985. 2 Fig, 6 Tab, 64 Ref.

Descriptors: *Monitoring, *Polychlorinated biphenyls, *Hexachlorocyclohexanes, *Mosses, *Bioindicators, Indicators, Organic compounds, Water pollution effects, Fate of pollutants, Pesticides.

The use of aquatic bryophytes for the monitoring of polychlorinated biphenyls (PCBs) and chlorinated pesticides alpha-, beta-, and gamma-HCH in freshwaters was investigated. Concentrations of alpha- and beta-HCH in Cinclidotus danubicus from the Saone (France) were below the detection limit. The contamination of the mosses by gamma-HCH did not vary much along the course of the river even though the site farthest downstream appeared less contaminated than the three other sites located in more agricultural areas. Polychlorinated biphenyls were detected at the four sites studied with no significant variation along the course of the river. Concentations of alpha-, beta- and gamma-HCH in water samples from Les Mees, 4 km downstream from a discharge site indicate the extreme contamination of the Durance. Polychlorinated biphenyl concentrations were below the detection limit. A progressive increase in the contaminant concentrations in C. danubicus transplanted to the polluted stretch of the river was observed. Polychlorinated biphenyls were detected in all moss samples with slight variations between sites and no significant change as a function of time. (Baker-IVI)

OCCURRENCE AND TRANSPORT OF ORGANIC MACROCONTAMINANTS IN THE DULUTH-SUPERIOR HARBOR,
Wisconsin Univ.-Superior. Center for Lake Superior Environmental Studies.
D. A. Bahnick, and T. P. Markee.
Journal of Great Lakes Research, Vol. 11, No. 2, p 143-155, 1985. 2 Fig, 7 Tab, 29 Ref. Dept. of Commerce grant NA 800AA-D-00086.

Descriptors: *Fate of pollutants, *Duluth-Superior Harbor, *Great Lakes, *Organic compounds, Pollutant transport, Lake sediments, Suspended sediments, Polychlorinated biphenyls, Aromatic hydrocarbons, Pentachlorophenol.

The Duluth-Superior harbor is a major Great Lakes port serving about 10,000 commercial and recreational vessels annually. The nature and magnitude of certain organic microcontaminants associated with harbor sediments and suspended particulate matter subject to transport to Lake Superior were investigated. The microcontaminants included polychlorinated biphenyls (PCBs), polycyclic aromatic hydrocarbons (PAH), and pentachlorophenol (PCP). The results of initial screening of particulate samples obtained from Duluth harbor in 1980 identified about 200 compounds in four extract fractions. The compound types consisted mainly of hydrocarbons, organic acids, esters, and alcohols. In addition some amines, ketones, aldehydes and phenols were detected. These compounds appear to be primarily plant decomposition products. GC/MS analysis in 1982 suggests the presence of a very large number of compounds, particularly in sediment sample extracts. Most appear to be naturally occurring organics. Some PAH compounds were also identified. Dichlorobenzene was the only halogenated compound identified from this data. In 1983, particulates were sampled in yet another site. Five PAH compounds were identified by retention times. PCP was detected in sediments and particulates collected from sites 1 and 2 in Duluth Harbor in 1982. Particulate samples contained higher concentrations of PCBs than did sediments. This may be due to a larger surface area and a higher organic content. Considering the concentration of PCBs in water and particulates in conjunction with average suspended solids levels, it was calculated that 91% of the PCBs were dissolved in water and 19% associated with suspended particles. Suspended solid transport of PCBs and PAH to Lake Superior is less than 0.01% of airborne transport. (Baker-IVI)

Descriptors: *Organic compounds, *Halogenated hydrocarbons, *Fish, *Water pollution sources, Lake Huron, Lake Superior, Great Lakes, Tributaries, Industrial wastes, Fate of pollutants, Pesticides, DDT.

Analyses were made on composite samples of fish taken from some of the major tributaries and embayments of Lake Superior and Lake Huron for halogenated xenobiotics. A good correlation was noted between the areas of industrial and urban development and the abundance, as well as variety, of industrial pollutants and pesticides in fish. Findings suggest that Saginaw Bay acts like a sink for pollutants from the area, especially for very hydrophobic compounds that are associated with suspended matter. The major source for PBBs seems to be located around the Pine River and Chippewa River areas, while PCBs are more abundant Chippewa, Tittabawassee, and Flint River PCTs seems to have sources near the Fli Saginaw rivers and, surprisingly, in the Kew Bay area. A similar pattern was noted f PCDEs except that they were also found Chippewa and Tittabawasee rivers but not Keweenaw Bay. It is interesting to note th concentrations of total DDTs in the Pine and Chippewa Rivers fish, as well as the pr of DDT itself in Pine River fish, indica possible source for these chemicals. (Bak

ACIDIFICATION OF GEORGIAN BAY RI ESTIMATED BY MODIFICATIONS OF WRIGHT-HENRIKSEN MODEL,
Department of Fisheries and Oceans, Owen (Ontario). Great Lakes Fisheries Research B
M. G. Johnson.
Journal of Great Lakes Research, Vol. 11, N 163-170, 1985. 6 Fig, 2 Tab, 8 Ref.

Descriptors: *Georgian Bay, *Ontario, *F pollutants, *Acidification, Acid rain, Alk Mathematical models, Anions, Organic pounds, Sulfates, Hydrogen ion concentratio

Major ion composition of fresh waters can b to estimate temporal changes in alkalinity a caused by loadings of sulfuric acid from the phere. In the Georgian Bay rivers organic must be considered, but road salt additio considerably more important than minor inputs. Nineteen rivers tributary to Georgia Lake Huron were sampled at the time of freshet in 1980-1983, and modified versions Henriksen-Wright model were used to m acidifiication of these river systems by esti loss of alkalinity and sulfate concentrations background sulfate levels. Spring freshet da used to assess acidification at times of e conditions, which likely are of more signific aquatic life. While seasonal variations in ac tion have not been examined, springtim charges should be more representative of th fication stress on these systems. Alkalini mates, averaged for all rivers, were 107-147 eq/L for various modifications and net sulfa mates averaged 108-125 micro-eq/L. Both ures of acidification increased with proxi Sudbury. The decrease in alkalinity, 45-166 eq/L for the 19 rivers, was related to the variability in atmospheric acid loadings, wi pH decrease, 0.2-1.6 units, reflected as w original buffering of each river. Organic were important in achieving cation-anion ba in interpretation of pH, and in modification Wright-Henriksen model. (Baker-IVI)

Descriptors: *Rocky Mountains, *Colorado, *Acid rain, Alkalinity, Rainfall, Alpine lakes, Watersheds, Hydrogen ion concentration.

Increased fossil fuel consumption in California, the Great Basin, or the upper or lower Colorado River drainage regions could lead to increased acidity of precipitation in the Rockies. The occurrence of acid precipitation at a remote and sensitive location in the Colorado Rockies brought about a long term study of the precipitation and surface waters of the western slope. The site is distant from highways, point sources, and major urban areas, and receives consistently acidic precipitation. The resulting data provide a means of assessing the present sensitivity of watersheds in the region to acidification and ultimately will allow determination of trends. The volume-weighted average pH for summer events was 4.61, for winter events was 5.11 and for the entire period was 4.91. Within the watershed, both low- and medium-alkalinity surface waters exist. Weekly alkalinity measurements ranged from 10 to 70 micro-eq/l in the former and 100 to 900 micro-eq in the latter. The findings demonstrate the occurrence of acid precipitation and the susceptibility to acidification of alpine lakes in this area. (Baker-IVI)

PARTITIONING OF HEAVY METALS (FE, MN, CD, PB, CU, ZN, CO, NI AND AS) AND P INTO SELECTIVE CHEMICAL FRACTIONS IN SEDIMENTS FROM LAKE KOJIMA (IN JAPANESE),
S. Nakashima, M. Yagi, and I. Aoyama.
Nogaku Kenkyu, Vol. 60, No. 4, p 157-169, March, 1985. 12 Fig, 13 Ref.

Descriptors: *Lake Kojima, *Okayama Prefecture, *Japan, *Lake sediments, *Heavy metals, *Phosphorus, Iron, Manganese, Cadmium, Cadmium, Lead, Copper, Zinc, Cobalt, Nickel, Arsenic, Metals, Nutrients, Particle size, Clays, Organic matter, Silicates, Sulfides.

To investigate the mechanism of metal accumulation in the sediment of Lake Kojima, Okayama Prefecture, Japan, surface sediments (10 samples) were collected and analyzed for Fe, Mn, Cd, Pb, Cu, Zn, Co, Ni, As and P. Partitioning of these metals and P into mineral and organic fractions was determined with selective chemical leaching techniques for sediment samples. Iron, Ni, and to a lesser degree, Co and As were contained in larger amounts in the silicate fraction, than in the non-silicate fractions. Arsenic, Co and Ni were concentrated mainly in the hydrous Fe/Mn oxide, sulfide and organic phases, and Fe was concentrated in the hydrous oxide and sulfide phases. The contents of Mn, Cd, Pb, Cu, Zn and P were lower in the silicate fractions than the non-silicate fractions, especially that of Cd. Manganese was fairly well distributed in all fractions, being dominant in the exchangeable, hydrous oxide and carbonate fractions. A large proportion of Cd, Pb, Cu, Zn and P was concentrated in the exchangeable (especially Cd), hydrous oxide, sulfide and organic fractions. Particularly, the contents of these elements in these four fractions were higher in sediments from the mouths of the Rivers Kurashiki and Sasagase which flow into the lake than in sediments from the lake. The contents of Mn, Cd, Pb, Cu, Zn and P in the silicate fractions were nearly the same in both fine-textured and coarse-textured sediments. Heavy metals and P in the fine-textured sediments were more highly concentrated in the hydrous oxide, sulfide and organic fractions than the coarse sediments. As a result, the total contents of these elements were higher in fine-textured than in coarse-textured sediment. These results indicate that heavy metals and P released by human activity are carried by the rivers into Lake Kojima, are adsorbed on hydrous Fe/Mn oxides and/or clay, are associated with organic matter or absorbed by living things, and are then precipitated and fixed in the sediment. (Author's abstract)

ASSESSMENT OF POLLUTION HISTORY FROM RECENT SEDIMENTS IN LAKE VANAJAVESI, SOUTHERN FINLAND. I. SELECTION OF REPRESENTATIVE PROFILES, THEIR DATING AND CHEMOSTRATIGRAPHY,
Helsinki Univ. (Finland). Dept. of Zoology.
P. H. Kansanen, and T. Jaakkola.
Annales Zoologici Fennici, Vol. 22, No. 1, p 13-55, 1985. 29 Fig, 8 Tab, 135 Ref.

Descriptors: *Lake sediments, *Water pollution, *Lake Vanajavesi, *Finland, Radioactive dating, Wood wastes, Heavy metals, Industrial wastes, Copper, Zinc, Cesium radioisotopes, Plutonium, Cadmium.

Surficial sediments were sampled from eutrophic Lake Vanajavesi (Finland) using 79 short sediment cores. The lake has been subjected to waste water loading for 100 years mainly from the wood processing industry. Of the analyzed heavy metals, zinc, cadmium and copper showed clear enrichment in the selected profiles. For these elements the maximum cultural enrichment factors were 84.6, 6.1, and 2.9, respectively. Zinc was the best tracer for mapping the areal distribution and for giving historical records of industrial waste waters due to the high point source loading from the chemical industry that has occurred since 1943. Dehydroabietic acid content in sediment indicated an abrupt increase since the 1940s in the loading from the wood processing industry. Due to mixing, the peak of Cs-137 and Pu-239,240 was deeper than expected on the basis of mean sedimentation rate. The time scale derived from Cs-137 and Pu-239,240 distribution was in accordance with the zinc stratigraphy and known history of zinc loading. (Baker-IVI)

ASSESSMENT OF POLLUTION HISTORY FROM RECENT SEDIMENTS IN LAKE VANAJAVESI, SOUTHERN FINLAND. II. CHANGES IN THE CHIRONOMIDAE, CHAOBORIDAE AND CERATOPOGONIDAE (DIPTERA) FAUNA,
Helsinki Univ. (Finland). Dept. of Zoology.
P. H. Kansanen.
Annales Zoologici Fennici, Vol. 22, No. 1, p 57-90, 1985. 12 Fig, 11 Tab, 75 Ref.

Descriptors: *Lake Vanagavesi, *Finland, *Eutrophication, *Aquatic insects, Lake sediments, Population dynamics, Midges, Water pollution effects, Eutrophic lakes.

The present midge fauna of Lake Vanajavesi (Finland) was compared to subfossil remains from sediment profiles as part of a study of the development of Lake Vanajavesi during the industrial period of its history in the 19th and 20th Centuries. In Lake Vanajavesi eutrophication has led to the replacement of an oligotrophic Microspectra - Monodiamesa community by a eutrophic Chironomus anthracinus community in the first decades of this century. The replacement took place at a relatively low leading level; about 1/10-1/15 of the present total wastewater load. This is in accord with the established fact that Vanajavesi, like many other lakes in the clay area of southern Finland, was originally eutrophic. The dysoligotrophic features are due to a high humus load. Artificial lowering of the water levels also probably adversely affected the food availability for the midge fauna. A relatively slight cultural impact was needed to cause a return of the eutrophic conditions. In the further succession from a Chironomus anthracinus community to a Chironomus plumosus community, and finally to the disappearance of the deep water fauna, the key factor appears to have been the oxygen content of the water. The oxygen state of Lake Vanajavesi depends not only on the production level of the lake, but more on the direct impact of waste water loading having a high BOD. (Baker-IVI)

CHANCE-CONSTRAINED/STOCHASTIC LINEAR PROGRAMMING MODEL FOR ACID RAIN ABATEMENT - I. COMPLETE COLINEARITY AND NONCOLINEARITY,

Waterloo Univ. (Ontario). Dept. of Civil Engineering.
J. H. Ellis, E. A. McBean, and G. J. Farquhar.
Atmospheric Environment, Vol. 19, No. 6, p 925-927, 1985. 8 Fig, 5 Tab, 22 Ref.

Descriptors: *Acid rain, *Statistical analysis, *Computer programs, *Linear programming, *Model studies, Sulfur dioxide, Fate of pollutants, Path of pollutants, Water pollution prevention.

A Linear Programming model is presented for development of acid rain abatement strategies in eastern North America. For a system comprising of 235 large controllable point sources and 83 uncontrolled area sources, it determines the least-cost method of reducing SO2 emissions to satisfy maximum wet sulfur deposition limits at 20 sensitive receptor locations. The purely deterministic model is extended to a probabilistic form by incorporating the effects of meteorologic variability on the long-range pollutant transplant processes. These processes are represented by source-receptor-specific transfer coefficients. Experiments for quantifying the spatial variability of transfer coefficients showed their distributions to be approximately lognormal with logarithmic standard deviations consistently about unity. Three methods of incorporating second-moment random variable uncertainty into the deterministic LP framework are described: Two-Stage Programming Under Uncertainty (LPUU), Chance-Constrained Programming (CCP) and Stochastic Linear Programming (SLP). A composite CCP-SLP model is developed which embodies the two-dimensional characteristics of transfer coefficient uncertainty. Two probabilistic formulations are described involving complete colinearity and complete noncolinearity for the transfer coefficient covariance-correlation structure. Complete colinearity assumes complete dependence between transfer coefficients. Complete noncolinearity assumes complete independence. The completely colinear and noncolinear formulations are considered extreme bounds in a meteorologic sense and yield abatement strategies of largely didactic value. Such strategies can be characterized as having excessive costs and undesirable deposition results in the completely colinear case and absence of a clearly defined system risk level (other than expected-value) in the noncolinear formulation. CHEMICAL ZONATION IN GROUNDWATER OF THE CENTRAL PLAINS, CANTERBURY,
North Canterbury Catchment Board, Christchurch (New Zealand).
R. J. Burden.
Journal of Hydrology (New Zealand), Vol. 23, No. 2, p 100-119, 1984. 6 Fig, 3 Tab, 23 Ref.

Descriptors: *Central Plains, *Groundwater, *New Zealand, *Nitrates, Zones, Land use, Chlorides, Water pollution sources, Groundwater pollution, Leaching, Fertilizers, Pastures, Wastewater pollution.

The relationship between land use and nitrate levels in Central Plains (New Zealand) groundwater was studied. The principal sources of nitrate are quantified and the movement and accumulation of nitrate in groundwater are described. Groundwater samples were obtained from about 600 wells over the period 1977 to 1983. Major ion analyses were conducted on water from about 300 wells in the specific study area, mostly located near Christchurch City or near suspected point sources of contamination. The remainder were analyzed for both nitrate and chloride or nitrate alone. The Central Canterbury Plains consist of a vertical sequence of coalesced glacial outwash and postglacial alluvial fans deposited by the Rakaia, Selwyn and Waimakariri Rivers. Several sources contribute to nitrate concentrations in Central Plains groundwater. Dryland pasture is the principal source of nitrate affecting the quality of the groundwater. Cropping is widespread on the deeper soils on the Plains with the amount of nitrate leached from cropland being dependent on soil depth and the timing of irrigation and fertilizer applications. Domestic and industrial sewage from most of the Christchurch metropolitan area and from Lincoln township is disposed, via treatment plants, to surface water and therefore does not affect groundwater quality. The major point sources of waste and irrigated animal effluent together contribute only about 5% of the total nitrate load in Central Plains groundwater. The groundwater has been divided into three chemical zones. Zone 1 lies in regions of recharge from rivers; 2 includes unconfined and semi-confined groundwater down to 60 m below the water table, and some shallow confined groundwater, and 3 comprises all deep circulating groundwater. COPPER DISSOCIATION FROM ESTUARINE HUMIC MATERIALS,
North Carolina Univ. at Chapel Hill. Dept. of Environmental Sciences and Engineering.
D. L. Olson, and M. S. Shuman.
Geochimica et Cosmochimica Acta, Vol. 49, No. 6, p 1371-1375, 1985. 5 Fig, 2 Tab, 37 Ref. NSF grant OCE-7914592.

Descriptors: *Kinetics, *Copper, *Humic acids, *Estuarine environment, Metals, Chemical reactions, Organic matter, Chemical kinetics.

The kinetics of Cu-organic binding in an estuary is examined. Previous data analysis methods have been extended by developing a nonlinear kinetic model for the simultaneous, first order dissociation reactions of CuHM (Cu humic material). The model gives a kinetic spectrum which is used to examine how CuHM rate constants are distributed among bound Cu(II) and how they vary with molecular size and sampling site along a southeastern U.S. estuary. A significant portion of bound Cu(II), 28-54%, reacted with $k > 40$/sec. In general, variations were observed only between size fractions. Since a major portion of Cu(II) bound to HM is labile, it cannot be generally assumed that dissociation is so slow that complexes can be separated from free metal without disturbing the Cu(II)-HM equilibrium. The kinetic spectrum model, described as a set of independently and simultaneously reacting Cu(II) binding sites, can easily accommodate an unknown number of components and a wide range of constants. These features are critical for valid application to a metal-HM kinetic system and interpretation of data. The model also provides a means of optimizing the time range of kinetic measurements by inspection of preliminary data. (Baker-IVI)

PARTITIONING AND TRANSPORT OF METALS ACROSS THE O2/H2S INTERFACE IN A PERMANENTLY ANOXIC BASIN: FRAMVAREN FJORD, NORWAY,
Washington Univ., Seattle. School of Oceanography.
L. Jacobs, S. Emerson, and J. Skei.
Geochimica et Cosmochimica Acta, Vol. 49, No. 6, p 1433-1444, June, 1985. 7 Fig, 6 Tab, 23 Ref. NSF grant OCE 82-13927-1.

Descriptors: *Metals, *Transport, *Framvaren Fjord, *Norway, Anoxic conditions, Manganese, Iron, Cobalt, Nickel, Copper, Zinc, Cadmium, Solubility, Sulfides, Marine waters.

The zonation of geochemical processes ope in anoxic basins provides a unique opportun weigh their relative importance in the solid ous phase partitioning and transport of across the O2/H2S interface. Water sampl suspended particulates were collected from varen Fjord, Norway. The metals Mn, Fe, Cu, Zn, and Cd showed systematic variati their response to the processes of metal precipitation and metal oxide O2/H2S in cycling. For manganese sulfide a nearly co ion activity product (IAP) is maintained th out the water column. The calculated man sulfide IAP is undersaturated with respe known pure phases, however, the existen manganese as a trace component in fram pyrite (1%) may explain this undersatura solid solution equilibrium is assumed. Tra metals show involvement in both metal formation and metal oxide interface cyclin intensity of this cycling is quantified with model, with the resulting hier Mn>Co>Fe>Ni. The Class B metals sh involvement in interface cycling and stro volvement in metal sulfide precipitation abrupt concentration drop across the O interface observed for copper, zinc and ca translates to a residence time of one year fo metals in the oxic surface water. Surface c trations and the common transport mechani scribed for copper, zinc and cadmium are d coupled to the sediment enrichments (rela the lithogenic component) observed for metals, suggesting that anoxic basins act as lent Class B metal traps. The source of th ment excess could be explained by atmos fallout for cadmium and zinc. (Baker-IVI)

LONGITUDINAL DISPERSION IN A FOREST STREAM,
Universite Catholique de Louvain, Louvain-la-Neuve (Belgium). Dept. des Sciences du Sol.
C. Legrand-Marcq, and H. Laudelout.
Journal of Hydrology, Vol. 78, No. 3/4, p 317-324, June, 1985. 2 Fig, 14 Ref.

Descriptors: *Streams, *Dispersion, *Path of pollutants, Solute transport, Stream pollution, Differential equations, Stagnant water, Streamflow.

A forest stream typical of those found in SE Belgium and NE France has been studied with respect to the parameters determining the dispersion of a non-reactive solute in a streamflow with stagnant zones. Non-linear adjustment of an analytical solution of two partial differential equations describing longitudinal dispersion and solute exchange between main stream and stagnant water provided a set of parameters describing satisfactorily the experimental results. The dead-zone fraction diminished very rapidly as soon as the flow rate increased beyond a fairly low value and remained constant thereafter. The longitudinal dispersion coefficient followed an inverse pattern but in a somewhat less regular way. Attempts were made to correlate these changes with the Darcy-Weisbach friction factor. Descriptors: *Polycyclic aromatic hydrocarbons, *Anthracene, *Naphthalene, *Degradation, *Mineralization, *Marine sediments, Intertidal zone, Biodegradation, Acclimatization, Fate of pollutants, Aromatic compounds, Hydrocarbons, Microorganisms, Dissolved oxygen, Temperature effects.

The degradation of the polynuclear aromatic hydrocarbons (PAHs) anthracene and naphthalene by the microbiota of intertidal sediments as investigated in laboratory studies. No mineralization of either PAH was observed in the absence of oxygen. Both rates and total amounts of PAH mineralization were strongly controlled by oxygen content and temperature of the incubations. Inorganic nitrogen and glucose amendments had minimal effects on PAH mineralization. The rates and total amounts of PAH mineralized were directly related to compound concentration, pre-exposure time, and concentration. Maximum mineralization was observed at the higher concentrations (5 to 100 micro-g/g) of both PAHs. Optimal acclimation to anthracene and naphthalene (through pre-exposures to the compounds) occurred at the highest acclimation concentration (1,000 ppm). However, acclimation to a single concentration (100 ppm) resulted in initial relative mineralization rates over a range of re-exposure concentrations (1 to 1,000 ppm) being nearly identical. Maximum mineralization of both PAHs occurred after intermediate periods (1 to 2 weeks) of pre-exposure. The fraction of the total heterotrophic population capable of utilizing anthracene or naphthalene as sole carbon source was also greatest after 2 weeks. (Author's abstract)

Descriptors: *Pentachlorophenol, *Microbial degradation, *Fate of pollutants, Stream pollution, Dissolved oxygen, Chlorinated phenols, Substrates.

Outdoor artificial streams were treated continuously with pentachlorophenol (PCP) for 88 days during the summer of 1983. The contributions of different stream compartments (microbial habitats) to microbial degradation of PCP were determined in a stream treated with 144 micro-g of PCP per liter. The 488-m long stream was composed of mud-bottomed pools alternating with gravel riffles. PCP loss in the stream attributable to microbial degradation after an adaptation period was in the range of 55 to 74%. Contributions to PCP loss were determined for rock surface (epilithic), macrophyte surface (epiphytic), sedimentary, and water column communities by measuring rates of PCP disappearance in stream water, containing ambient concentrations of PCP, in contact with representative compartmental samples. The specific capability, in units of micrograms of PCP per hour per square meter of stream cross-sectional area (macrophytes at maximum plant density, water column at mean depth, upper 10-cm layer of gravel), followed the order rock surface > macrophytes > sediment approximately = water column. The compartmental contribution to total stream losses in units of grams per hour followed the same order, although the differences were smaller. The rate of PCP disappearance in the water column above sediment cores followed the order oxygen-rich > oxygen-poor approximately = anaerobic > sorption-only conditions. The large difference in specific capability between the rock surface and sediment compartments could be attributed to oxygen deficiency (because of chemical and biological oxygen demand) in the sediments. Free-floating and particle-attached organisms in the water column were important to PCP biodegradation. (Author's abstract)

ESTIMATES OF AVERAGE MAJOR ION CONCENTRATIONS IN BULK PRECIPITATION AT TWO HIGH-ALTITUDE SITES NEAR THE CONTINENTAL DIVIDE IN SOUTHWESTERN COLORADO,
Geological Survey, Lakewood, CO.

M. M. Reddy, and H. C. Claassen.
Atmospheric Environment, Vol. 19, No. 7, p 1199-1203, 1985. 3 Fig, 1 Tab, 15 Ref.

Descriptors: *Precipitation chemistry, *Altitude, *Colorado, Calcium, Sulfates, Nitrates, Seasonal variation, Atmospheric deposition.

The composition of bulk precipitation from two high-altitude sites, established in 1971 near the Continental Divide in southwestern Colorado, has been monitored by season during the past decade. Calcium ions are the predominant cationic species; sulfate is the major anionic constituent. Bulk precipitation major ion concentrations exhibit log-normal distributions. Representative mean and standard deviation values for the major inorganic ionic species present in bulk precipitation have been calculated for three years of consecutive seasons. Standard deviations for all species, except nitrate, are similar. For two years of data grouped into quarters, deviations from mean values fall well within the plus or minus two standard deviation limit. There does not seem to be a systematic deviation from the mean concentration values, with respect to either ionic component or season. (Author's abstract)

Descriptors: *Heavy metals, *Elbe River, *Estuaries, *Germany (Federal Republic), Water pollution, Copper, Cadmium, Lead, Nickel, Cobalt, Resuspension, Turbidity, Fate of pollutants.

Surface water samples were collected during missions in 1977, 1978, 1980 and 1983 at different sampling stations along the tidal Elbe, from river km 632 downstream from Hamburg to the outer end of the estuary. Special care was taken to minimize contamination during sampling, handling and analysis. Within the tidal Elbe five distinct zones of substantial anthropogenic heavy metal pollution inputs can be detected. An attempt is made to define anthropogenic background levels, which are extremely low for the dissolved trace metals Cd and Pb; 35 and 65 ng/kg, respectively. The level of dissolved Cu is 2200 ng/kg. Total baseline levels of Cd, Pb and Cu are, respectively, 120, 2500 and 4200 ng/kg. In the five river zones affected by anthropogenic trace metal inputs, distinctly larger maximum levels can occur. They decrease to the background values after mixing with the main water body. More elevated levels caused by re-suspension in the mixing zone with maximum turbidity can be assumed. Nickel and Co data are from one mission only. The order of magnitude of the trace metal input from the Elbe into the sea is evaluated. (Author's abstract)

FATE OF THE PYRETHROID INSECTICIDE DELTAMETHRIN IN SMALL PONDS: A MASS BALANCE STUDY,
Department of Fisheries and Oceans, Winnipeg (Manitoba). Freshwater Inst.
D. C. G. Muir, G. P. Rawn, and N. P. Grift.
Journal of Agriculture and Food Chemistry, Vol. 33, No. 4, p 603-609, July/August, 1985. 6 Fig, 5 Tab, 27 Ref.

Descriptors: *Fate of pollutants, *Path of pollutants, *Insecticides, *Deltamethrin, *Ponds, Fish, Plants, Aquatic plants, Degradation products, Sediments, Water analysis, Pyrethrins.

A quantitative determination was made of the relative importance of various pathways of pollutants such as volatilization, degradation in water and sediment, and uptake by fish and plants, following application of C-14 labeled deltamethrin to water under field conditions. A single application of the insecticide was made at 10 g/ha to two small outdoor ponds, 17 sq m in surface area. Initial concentrations of the insecticide in filtered water ranged from 1.28 to 2.50 microg/L. Deltamethrin rapidly partitioned into suspended solids, plants, sediment, and air, with a half life of 2-4 hr in water. Duckweed and a submerged pondweed accumulated deltamethrin concentrations ranging from 253 to 1021 ng/g, respectively, at 24 hr posttreatment. Sediments were the major sink for radioactivity at 306 days posttreatment, and intact deltamethrin was present at concentrations ranging from 3 to 5 ng/g. Deltamethrin levels in air above the water ranged from 10-100 ng/cu m during a 48 hr monitoring period following application. Fathead minnows accumulated levels of extractable radioactivity 248-907-fold higher than concentrations in water at 24 hr posttreatment, but no fish mortality was observed. (Baker-IVI)

SURVEY OF 2,3,7,8-TETRACHLOROBIDENZO-P-DIOXIN IN FISH FROM THE GREAT LAKES AND SELECTED MICHIGAN RIVERS,
Food and Drug Administration, Detroit, MI. Pesticide and Industrial Chemical Research Center.
N. V. Fehringer, S. M. Walters, R. J. Kozara, and L. F. Schneider.
Journal of Agricultural and Food Chemistry, Vol. 33, No. 4, p 626-630, 1985. 3 Fig, 2 Tab, 12 Ref.

Descriptors: *Great Lakes, *Michigan, *Rivers, *Pesticide residues, *Tetrachlorodibenzo-p-dioxin, Saginaw Bay, Lake Huron, Tittabawassee River, Lake Ontario, Dioxin.

Residues of 2,3,7,8-tatrachlorodibenzo-p-dioxin (TCDD) were measured in fish taken from the Great Lakes. Fish from the Saginaw Bay (Lake Huron), the Tittabawassee River in Michigan, and Lake Ontario contained the highest levels of contamination. No TCDD residues at or above the minimum confirmable level of 10 ppt were found in fish from Michigan rivers other than the Tittabawassee. Comparison of the current findings with the results of an earlier study, 1983, suggests a decrease in residue levels with time. Detectable levels of TCDD were found only in carp, catfish, salmon, white perch and trout. No residues at or above the 10 ppt level were found in sucker, whitefish, yellow perch, walleye, bullhead, crappie, bowfin, rockbass, buffalo, white bass, and sheepshead. (Baker-IVI)

OF PCB IN HUDSON RIVER DIMENTS,
ytechnic Inst., Troy, NY. Dept. of ng.

Northeastern Environmental Science, Vol. 3, No. 3/4, p 190-196. 5 Fig, 14 Ref.

Descriptors: *Polychlorinated biphenyls, *Fate of pollutants, *Bed load, *Hudson River, *Sediment transport, Chlorinated hydrocarbons, Path of pollutants, Particle size.

In order to measure the transport of a contaminant on river sediments, the sediment transport relations must be determined. In this project, bedload sediment transport in the upper Hudson River was first determined. The bedload samples were analyzed for PCB concentrations, which enabled the determination of PCB transport via the bedload sediments. This is one of a very few investigations that deal with the transport of a toxic contaminant via bedload sediments. Two different types of bedload samplers were utilized: the Helley-Smith bedload sampler, which is a sampler often used by the U.S. Geological Survey; and a Bogardi type bedload sampler, which was developed for studies in New York State rivers and steams. The two samplers complemented each other, and it was possible to obtain satisfactory bedload samples at all times, even under extreme flood flow conditions. During the study period, a wide range of flows were encountered in the Hudson River, enabling the determination of a very satisfactory bedload sediment-discharge relationship. The PCB transport-discharge relation does not correlate as well as the sediment-discharge relation, but this is as expected. The various size fractions of the bedload samples were analyzed for PCB and percent volatiles. There was no correlation between PCB concentration and grain size. However, there was a tendency for higher PCB concentrations to occur in the larger sizes, the opposite of what one might expect. This is attributed to the organics in the sediments, a conclusion borne out by the observation that PCB concentration correlates well with percent volatiles. (Author's abstract)

TRENDS IN PCB TRANSPORT IN THE UPPER HUDSON RIVER,
Lawler, Matusky and Skelly Engineers, Pearl River, NY.
G. Apicella.
Northeastern Environmental Science, Vol. 3, No. 3/4, p 196-201. 4 Fig, 1 Tab, 5 Ref.

Descriptors: *Polychlorinated biphenyls, *Hudson River, *New York, *Fate of pollutants, *Sediments, Chlorinated hydrocarbons, Sediment transport, River flow, Model studies, Water pollution sources.

Because of the high affinity of polychlorinated biphenyls (PCBs) for sediment, PCB movement is controlled essentially by the hydraulic changes that affect sediment transport. The transport of PCBs was analyzed for the Upper Hudson River (New York) based on data collected by the U.S. Geological Survey (USGS) from 1976 to 1983 - the period following the major abatement of PCB discharges. Data for temporal trends in PCB concentration at Waterford, New York, were analyzed while accounting for the year-to-year variability in observed flows. A linear regression of PCB concentration vs flow was made using data that are separated into low- and high-flow ranges, that is, below and above 10,000 cfs. The regressions account for the dependence of PCB concentration on the flow at the time of the sampling and enables a comparison among years of PCB data that are normalized for flow. Decreases in PCB concentration over time are found for both flow ranges, suggesting that the riverbed source releases diminishing amounts of PCB to the overlying water. A multiple regression analysis was conducted with PCB concentration as the dependent variable and flow, time, and suspended sediment concentration as candidate independent variables. Results of this analysis confirm a significant trend toward decreasing PCB concentration with time. In addition to time, river flow is a second factor in determining PCB concentration. Suspended sediment concentration does not improve the regression equation significantly because its effect essentially duplicates that of flow, which is already included. An analytical framework for evaluating PCB transport through the Upper Hudson River was developed based on previously collected data. Evaluation procedures comprise extending the analyses of Waterford data to other sampling stations and integrating river flow, which has a long-term cycle of 20 years, into the computation of PCB transport. The effect of the cycle - which will soon enter a phase of generally increasing flow - on the driving force on PCB transport can be evaluated using these analytical approaches. (Author's abstract)

PCB TRANSPORT IN THE FT. EDWARD AREA,
New York State Dept. of Environmental Conservation, Albany.
T. J. Tofflemire.
Northeastern Environmental Science, Vol. 3, No. 3/4, p 203-208. 9 Fig, 1 Tab, 11 Ref.

Descriptors: *Polychlorinated biphenyls, *Hudson River, *New York, *Fort Edwards, *Sediments, *River beds, Chlorinated hydrocarbons, Organic carbon, Fate of pollutants, Path of pollutants, Water pollution sources.

Removal of the Ft. Edwards dam on the Hudson River (New York) in 1973 exposed coarse trashy sediment containing polychlorinated biphenyls (PCBs) and other contaminants. The fate of PCBs in the Ft. Edward area was analyzed with data on river water transport, air transport and dredging transport. The water transport of PCB's at Roger's Island is decreasing with time, although a small unidentified source of PCB north of Area 1 of the remnant deposits may still be present. From water sampling studies at low flow, it was shown that only 25% of the PCB's passing Rogers Island were coming from the east bank or channel. About 40% of the PCB's were coming from sources north of Area 1, with the remainder coming from the broad river bottom areas which are mostly rock. These upstream sources should be located an sampled by some type of integrating and concentrating systems that integrate PCB from water over several weeks. The remnant deposits appear to be scouring much less than before 1979. PCBs have been volatilizing from the remnant deposit sediments; air PCB values over the remnant areas are decreasing with time. The last sampling was in 1982. Depletion of PCB from the surface layer and the build up of organic carbon in the top soil due to increased vegetation on Areas 4 and 5 probably aids this process. EFFECTS OF DREDGING OPERATIONS ON NUTRIENT AND SUSPENDED SEDIMENT CONCENTRATIONS,
Army Engineer District, New York.
J. F. Tavolaro, and J. M. Mansky.
Northeastern Environmental Science, Vol. 3, No. 3/4, p 208-216. 6 Fig, 2 Tab, 18 Ref.

Descriptors: *Dredging, *Nutrients, *Suspended sediments, *Raritan Bay, *New York Bay, *New Jersey, Source of pollutants, Nitrates, Environmental effects, Ammonia, Phosphates.

In response to concerns about the potential impact of dredging operations to water quality, two monitoring efforts were undertaken. Concentrations of dissolved nutrients were monitored for hopper dredging operations in Raritan Bay, NY/NJ and concentrations of suspended sediment were monitored for clamshell dredging operations in the Upper Bay of New York Harbor. Concentrations of TKN, nitrate and total ammonia did not appear to be affected in the vicinity of the dredging. Total phosphate and orthophosphate appeared to decrease while nitrite appeared to increase, although the overall nitrite concentrations were low. Flumes of higher than ambient concentrations of suspended sediment did not persist more than 24 hours after dredging ceased. Maximum concentration ranged from several hundred milligrams per liter on the bottom to less than 100 mg/l on the surface within 60 meters of the dredge. Surface and bottom concentrations decreased rapidly with distance from the dredge and ranged from 20 to 30

mg/l at a distance between 210 meters and 350 meters. Ambient conditions were established within 480 meters on the surface and 570 meters on the bottom. (Author's abstract)

BACKGROUND LEVELS OF DISSOLVED/DISPERSED PETROLEUM RESIDUES IN THE GULF OF ST. LAWRENCE, 1970-79,
Bedford Inst. of Oceanography, Dartmouth (Nova Scotia). Atlantic Oceanographic Lab.
E. M. Levy.
Canadian Journal of Fisheries and Aquatic Sciences, Vol. 42, No. 3, p 544-555, March, 1985. 3 Fig, 8 Tab, 16 Ref.

Descriptors: *Gulf of St. Lawrence, *St. Lawrence Estuary, *Saguenay Fjord, *Water pollution sources, *Path of pollutants, *Hydrocarbons, Model studies, Fate of pollutants, Monitoring, Mixing.

A 10-yr program of monitoring the incidence and distribution of dissolved/dispersed petroleum residues in the Gulf of St. Lawrence confirmed that the major source is the Atlantic water that enters through Cabot Strait and demonstrated that a substantial decline in the background levels occurred during the mid-1970's. A model was developed to interpret the geographical distribution of the petroleum residues. The incidence and distribution of dissolved/dispersed petroleum residues in the waters of the Gulf of St. Lawrence and adjoining areas during the period 1970-79 could be interpreted in terms of general background levels pertaining to 'boxes' of water defined solely on the basis of oceanographic/geographic regimes. Since no relationship could be found between the concentration of these substances and depth or any of the other commonly measured oceanographic parameters and because the apparent differences between the concentration levels in neighboring boxes often were not significant, the background levels in the Gulf region at the time of each cruise could be accounted for by a simple model with four or five compartments. The present level, about 0.4 micro-g/L, is similar to those of other unpolluted areas off the east coast of Canada and in the Arctic where it appears that the input from atmospheric deposition exceeds those from accidental spills, deliberate discharges, and other point sources. Although small spills occur occasionally, their effects are usually local and short-term and have little lasting impact on the regional levels. Inputs of petroleum residues from land-based sources around the Gulf are presently insignificant except at the extreme upper reaches of the St. Lawrence Estuary and the Saguenay Fjord; even there the effect is highly localized because of dilution, sedimentation, and other processes of removal associated with the mixing of fresh and saline waters, and therefore, these sources do not make a significant contribution to the background level in the Gulf region as a whole. STORMWATER RUNOFF FROM HIGHWAYS,
Rhode Island Univ., Narragansett. Graduate School of Oceanography.
E. J. Hoffman, J. S. Latimer, C. D. Hunt, G. L. Mills, and J. G. Quinn.
Water, Air, and Soil Pollution, Vol. 25, No. 4, p 349-364, August, 1985. 3 Fig, 8 Tab, 29 Ref. NOAA grant NA80RAD00047 and EPA grant 68-04-1002.

Descriptors: *Runoff, *Storm runoff, *Highway effects, *Pawtuxet River, *Rhode Island, Highways, Water pollution sources, Hydrocarbons, Trace metals, Metals, Urban runoff, Water quality management.

During four rain events, stormwater runoff samples from Interstate Highway 95 in Rhode Island were collected and analyzed for petroleum hydrocarbons, 14 polycyclic aromatic hydrocarbons (PAHs) and a variety of trace metals. The concentrations were variable throughout the storm events and some of the components responded similarly and others differently depending on the source and form of the component in the runoff. Loading factors as a function of area and traffic volume were developed from the concentration and flow data. Application of the highway runoff loading factors to the Pawtuxet River adjacent to this interstate highway suggests that highway runoff could be the source of over 50% of the annual pollutant loads of solids, PAHs, Pb, and Zn entering this river. It is recommended that highways as a source of non-point pollution to receiving waterbodies should be included as a part of any river and estuarine water quality management planning exercise. Descriptors: *Precipitation chemistry, *Particulate matter, *Hydrogen ion concentration, *Alkalies, *India, Water pollution sources, Chemical composition, Acid rain, Calcium, Soil.

Rain water samples were collected over a period of a decade from 1974 in Pune, India, a city which is relatively free from industrial pollution. They were also collected at 4 places during 1974 in the region of Bombay which is highly industrialized. The samples were analyzed for major chemical components and pH. The ionic balance was computed. Samples were collected at Delhi during 1965 and 1966 and were analyzed for pH. The values were compared with those reported for 1978. The total suspended particles (TSP) were measured at Delhi during 1980 and analyzed for water soluble components. The rain water at all the places except near the industrial source was not acidic and was characterized by the presence of excess cations, particularly Ca. The acid rain near the industrial source was associated with excess anions, especially sulfate. The difference between the cations and anions was inversely proportional to the H(+) ion concentration. The pH of rain water at Delhi which was in the alkaline range during 1965 and 1966 remained alkaline after a period of 12 yr when the city developed industrially. The TSP in the region was rich with the basic components, mainly Ca, suggesting that the alkaline property of the soil dust is mainly responsible for neutralizing the acidic effects resulting from the anthropogenic gaseous pollutants. CATALYTIC EFFECT OF VARIOUS METAL IONS ON THE METHYLATION OF MERCURY IN THE PRESENCE OF HUMIC SUBSTANCES,
Swedish Environmental Research Inst., Goeteborg.
Y.-H. Lee, H. Hultberg, and I. Andersson.
Water, Air, and Soil Pollution, Vol. 25, No. 4, p 391-400, August, 1985. 6 Fig, 3 Tab, 30 Ref.

Descriptors: *Methylation, *Mercury, *Path of pollutants, *Humic substances, *Metals, Heavy metals, Fulvic acid, Manganese, Aluminum, Iron, Copper, Catalysis, Hydrogen ion concentration.

Methylation of Hg(2+) (Hg(NO3)2) in the presence of fulvic acid (FA) and various metal ions has been studied. The concentrations of Hg(2+) and FA ranged from 5 to 200 mg/L and 171 to 285 mg/L dissolved organic carbon respectively. The pH range was 3 to 6.5. FA was isolated from an acid brown-water lake by XAD-8 polymeric adsorbent. Methylmercury production in the dark during 2 to 4 days incubation at 30 C increased with increasing concentrations of Hg(2+ FA as well as with additions of metal ion mole/L). The observed catalytic activity ions followed the order Fe(3+) (Fe Cu(2+) approximately = Mn(2+) > The production of methylmercury had a mum around 4 to 4.5 at the condition (Author's abstract)

Bloody Run is a small creek that drains the Hyde Park hazardous waste dump in Niagara Falls (New York). Bloody Run Creek flows into the Niagara River, which is the major water source for Lake Ontario. Lake Ontario sediment cores were taken from the major sedimentation basins; sediment grab samples were collected from Bloody Run Creek, and the creek system adjacent to the Love Canal. Fish were sampled for the Niagara River, Lake Ontario, and the Little Niagara River. Sediment and fish samples were analyzed by capillary gas chromatographic mass spectrometry using negative ion methane chemical ionization. A series of bis(trifluoromethyl)-substituted polychlorinated biphenyls was discovered. These compounds were present in fish as well as in sediments, and their major source seems to be the Hyde Park dump in the city of Niagara Falls, NY. The concentrations of all compounds are 4-6 orders of magnitude higher in the Bloody Run Creek sediment than in Lake Ontario. (Moore-IVI)

Descriptors: *Phosphates, *Geological formations, *Runoff, *South Africa, Catchment areas, Water pollution sources, Non-point pollution sources, Bioavailability, Particulate matter.

A large degree of uncertainty is usually associated with phosphate loads estimated by means of export coefficients. Methods of reducing this uncertainty were investigated. Soluble and total phosphate export coefficients were calculated for 7 South African catchments over periods covering 3-5 years. Spatial variance in the export coefficients could largely be accounted for if catchments were grouped according to their geological characteristics; those in the upper Limpopo River drainage basin having igneous and those in the Vaal River drainage basin having sedimentary geological formations. A secondary, but nonetheless important factor contributing to the spatial variance of export coefficients was whether or not a particular catchment contained mainly point or mainly non-point sources. After catchments were grouped according to these two factors, 74%-99% of temporal variance of export coefficients could be explained by fitting linear regression equations to phosphate export vs runoff. The possible link between the bio-availability of particulate phosphorus and catchment geology is discussed. The significance of such a link, with regard to phosphate load estimates and making projections of future trophic status, is emphasized. (Author's abstract)

NITRATE BEHAVIOUR IN STREAMFLOW FROM A GRASSLAND CATCHMENT IN DEVON, U.K.,
Exeter Univ. (England). Dept. of Geography.
B. W. Webb, and D. E. Walling.
Water Research, Vol. 19, No. 8, p 1005-1016, 1985. 12 Fig, 3 Tab, 25 Ref.

Descriptors: *Nitrates, *Grasslands, *River Dart, *Devon, *England, Runoff, Seasonal variation, Storm runoff, Magnesium, Pollution load, Streams, Catchment area.

NO3-N levels and loadings in the River Dart, Devon, U.K. have been intensively monitored during the study period February 1975-January 1983, and NO3-N behavior in streamflow is compared with that of Mg which has predominantly contrasting origins and controls in runoff. A strongly developed annual regime characterizes daily mean NO3-N concentrations which peak at 4.5 mg/l in December and reach a minimum of 1.1 mg/l in early autumn, and this regime is reflected in a positive relationship between NO3-N concentration and discharge. Storm-period NO3-N behavior also exhibits a marked seasonal variation, and 'dilution' responses are typical of the winter period whereas a 'concentration' effect is more characteristic of summer months and is attributed to the influence of soil throughflow. Spring and autumn are associated with a transition in storm-period behavior, and the reaction of NO3-N concentrations during individual events or over a sequence of storms at any time of the year may also vary in response to a complex interplay of factors. NO3-N transport is more strongly biased towards storm events than is Mg, and more than 50% of the total NO3-N load was removed in only 10% of the study period. The mean annual NO3-N load for the study basin (24 kg/ha) is higher than that recorded in many grassland catchments of the U.K. but does not reflect an unusually high rate of fertilizer application. Unlike several other arable and grassland drainage basins studied in Britain, there is no evidence in the River Dart of a significant upward trend in NO3-N concentrations and loads since 1975. ROLE OF MN(2+)-RICH HYDROUS MANGANESE OXIDE IN THE ACCUMULATION OF ARSENIC IN LAKE SEDIMENTS,
National Inst. for Environmental Studies, Tsukuba (Japan). Water and Soil Environment Div.
T. Takamatsu, M. Kawashima, and M. Koyama.
Water Research, Vol. 19, No. 8, p 1029-1032, 1985. 4 Fig, 20 Ref.

Descriptors: *Arsenic, *Hydrous manganese oxide, *Lake sediments, Lake Biwa, Japan, Adsorption, Sediments, Manganese, Fate of pollutants.

The adsorption of As onto synthetic HMO and the association of Mn and As in the sediment cores from samples taken from Lake Biwa were examined. Arsenic has accumulated to high concentrations in the thin surface layers. The sedimentation rate suggests that the As-rich layers were deposited within the 4 years prior to sampling but no dramatic increase of As in flow to the lake was noted for that period. On the other hand, the coincident depth profiles of As and Mn concentrations in the cores and As concentrations up to 721 mg/kg in Mn concretions suggest that the surface accumulation of As may result from a dissolution-deposition cycle within the sedimentary column associated with that known to occur for Mn. In the absence of a divalent cation, no appreciable adsorption of arsenate onto HMO occurred between pH 6 and 8, a range often encountered in aquatic environments. There was a substantial increase in the amount of arsenate adsorbed by HMO in the presence of the divalent cations of Mn, Sr, Ba, and Ni. Hydrous Mn oxides, positively charged from the adsorption of Mn(2+) ions, could play a significant role in the accumulation of As on the surface of lake sediments. (Baker-IVI)

CHEMICAL CHARACTERIZATION OF STRATUS CLOUDWATER AND ITS ROLE AS A VECTOR FOR POLLUTANT DEPOSITION IN A LOS ANGELES PINE FOREST,
California Inst. of Tech., Pasadena. W.M. Keck Lab. of Environmental Engineering Science.
J. M. Waldman, J. W. Munger, D. J. Jacob, and M. R. Hoffmann.
Tellus, Vol. 37B, No. 2, p 91-108, April, 1985. 8

Fig, 4 Tab, 55 Ref. California Air Resources Board contract A2-048-32.

Descriptors: *Cloudwater, *Acid deposition, *Forests, *Los Angeles, *Acid rain, *California, Hydrogen ion concentration, Pine trees, Nitrates, Sulfates, Rain, Fog precipitation, Calcium, Potassium.

Highly concentrated, acidic stratus cloudwater was monitored as it intercepted a pine forest (Henninger Flats) 25 km northeast of Los Angeles, California. Observed pH values ranged from 2.06 to 3.87 for over 100 samples collected in 1982 and 1983 with a median value below pH 3. The ratio of nitrate/sulfate in cloudwater samples was between 1.5 and 2; rainwater at the same site had a ratio of approximately 1. The solute deposition accompanying several light, spring rains (summing to about 1% of annual rainfall) was a disproportionate fraction of the annual total: H(+), NO3(-) and SO4(2-) were about 20% or more. Based on a reasonable estimate of fog precipitation, deposition of sulfate, nitrate and free acidity due to intercepting stratus clouds may be of comparable magnitude as that due to the incident rainfall at Henninger Flats. Cloudwater that had deposited on local pine needles was collected. It was in general more concentrated than ambient cloudwater but with comparable acidity. Enrichment of K(+) and Ca(2+) in those samples and in through fall is believed to be due to leaching from foliar surfaces. Injury to sensitive plant tissue has been noted in the literature when prolonged exposure to this severe kind of micro-environment has been imposed. (Author's abstract)

MODEL FOR NITRATE LEACHING IN UNDISTURBED STRUCTURED CLAY SOIL DURING UNSTEADY FLOW,
Oxford Univ. (England). Soil Science Lab.
R. E. White.
Journal of Hydrology, Vol. 79, No. 1/2, p 37-51, July, 1985. 4 Fig, 3 Tab, 29 Ref.

Descriptors: *Nitrates, *Leaching, *Unsteady flow, *Clay, Mixing, Model studies, Unsaturated flow, Solute transport, Diffusion, Chlorides, Nitrification, Soil water, Mathematical equations.

A two-domain mixing model is described for predicting nitrate leaching during unsteady unsaturated flow through soil. The model assumes that water infiltrating the soil surface mixes incompletely with resident water to form a miscible transport volume, the size of which can vary with time. Changes in solute storage within the transport volume can occur by diffusion and biological transformations. Output from the transport volume is by drainage from a lower surface in the soil. The model's output was tested against the measured amounts of NO3-N leached from large undisturbed cores of structured clay soil during constant flux irrigation with 10 mM CaCl2. The average concentration of NO3(-) and Cl(-) in the soil solution was determined by extraction of small cores taken around the large cores prior to leaching. The rate of nitrification in the soil was also measured. The change in the transport volume with time was calculated from equations for the mass balance of water and Cl(-) in the transport volume. Knowing the transport volume, analogous equations in terms of NO3(-) were solved to predict the NO3(-) concentration in the effluent. Good agreement between predicted and observed NO3-N leached was obtained for cores showing divergent trends in NO3(-) leaching. A large difference between cores in the fraction of soil NO3-N leached (0.34 compared to 0.13) was attributed to the difference in the volume of high-nitrate soil water that mixed with infiltrating water to form the transport volume, and to differences in the distribution of NO3(-) between ped faces and ped interiors. The merit of incorporating the concept of a variable transport volume into a transfer function model for predicting NO3(-) leaching is briefly discussed. (Author's abstract)

A prototype study of the effects of dumping of anthropogenic wastes into the ocean has been the New York Bight Program of the National Oceanic and Atmospheric Administration. Particle-associated pollutants (totaling 10 to the 7th power metric tons per year) are introduced into the New York Bight by ocean dumping, estuarine discharge, sewage outfalls, eolian transport, and shipping waste and spillage. Because pollutants are associated with fine sediment particles, their fate in the New York Bight is intimately related to sediment transport processes. Sediment transport in the Bight is not a simple function of fluid transport. A combined flow boundary layer model was developed to improve near-bottom sediment transport predictions, and semiempirical relations were derived to predict resuspension of the small amounts of pollutant-bearing mud dispersed in the sand-dominated substrate. Oceanic and estuarine circulation processes dilute and transport the particles by a natural dispersal system that also tends to be highly distributive; particle-associated pollutants apparently seek the same sinks in the Hudson River shelf valley and intracoastal wetlands, regardless of their point of introduction. These sinks are inferred to be largely within the intracoastal zone of marshes, estuaries, and lagoons, and it is these areas that may determine the pollutant-related assimilative capacity of the New York Bight Apex as a whole. NUTRIENT RUNOFF LOSSES AS PREDICTED BY ANNUAL AND MONTHLY SOIL SAMPLING,
Agricultural Research Service, Durant, OK. Water Quality and Watershed Research Lab.
A. N. Sharpley, S. J. Smith, W. A. Berg, and J. R. Williams.
Journal of Environmental Quality, Vol. 14, No. 3, p 354-360, 1985. 4 Fig, 6 Tab, 24 Ref.

Descriptors: *Nutrients, *Runoff, *Soil sampling, *Prediction, Phosphorus, Nitrogen, Grasslands, Nutrient transport.

The transport of soluble and particulate P and N in runoff from several cropped and grassed watersheds in Oklahoma and Texas was related to the nutrient content of surface soil (0-50 mm) sampled monthly and annually (March) over a 2-yr period in an effort to improve the prediction of nutrient transport. For both monthly and annual soil samplings, the prediction of soluble P was good for events > 0.75 mm runoff (r values ranged from 0.57 to 0.92), but smaller events were poorly predicted. The nitrite content of runoff was not closely related to surface soil content (r values ranged from 0.17 to 0.58), precluding its accurate prediction in runoff. Prediction of both particulate P and total N concentrations of individual runoff events was improved using separate equations for grassed and cropped watersheds compared to a general equation. Even so, predicted mean annual flow-weighted concentrations and amounts of soluble P, particulate P, and total N using either monthly or annual soil nutrient data were significantly related to measured values at the 0.01 level and above (r values ranged from 0.57 to 0.97). Results indicate that seasonal variation in soil nutrient content had less effect on the predictive equations than rainfall and management characteristics. Consequently, these characteristics must be accounted for before the transport equations can be reliably used on an individual runoff event basis. (Author's abstract)

DESCRIPTION AND APPLICATION OF AN ANIMAL WASTE PHOSPHORUS LOADING MODEL,
Wisconsin Univ.-Madison.
I. C. Moore, and F. W. Madison.
Journal of Environmental Quality, Vol. 14, No. 3, p 364-369, 1985. 6 Tab, 30 Ref.

Descriptors: *Animal wastes, *Phosphorus loading, *Nutrients, Manure, Model studies, Fate of pollutants, Water pollution sources.

An animal waste loading model was developed to estimate total phosphorus (P) loadings from winter-spread manure, barnyards and feedlots, and aboveground manure storage facilities. Literature studies were used to establish the percentage of manure P which could potentially be carried in runoff from a specific manure source. Likewise, a critical distance over which manure polluted runoff must travel as overland flow in order for P to be reduced to background levels was established. The model was tested on a 328-ha watershed in Shawano County, WI, which is devoted to dairy agriculture and where surface water was monitored and intensive land use inventories were completed. For the years 1974 to 1976, the model predicted total P loadings from animal wastes of 96.0 kg/yr, of which 24.6 kg/yr or 26% was attributed to winter spreading, and the balance of 71.4 kg/yr or 74% to runoff from barnyards and above-ground storage facilities. The animal waste model was linked to a model estimating cropland losses of total P to develop a prediction of total P losses from the watershed. Comparison between predicted and monitored values suggested that the animal waste model was a useful tool for estimating total P losses from various waste handling practices on a long-term basis. As such, it will serve as a valuable planning tool for nonpoint source abatement programs. (Author's abstract)

SORPTION AND TRANSPORT OF HYDROPHOBIC ORGANIC CHEMICALS IN AQUEOUS AND MIXED SOLVENT SYSTEMS: MODEL DEVELOPMENT AND PRELIMINARY EVALUATION,
Florida Univ., Gainesville. Dept. of Physics.
P. S. C. Rao, A. G. Hornsby, D. P. Kilcrease, and P. Nkedi-Kizza.
Journal of Environmental Quality, Vol. 14, No. 3, p 376-383, 1985. 7 Fig, 2 Tab, 29 Ref.

Descriptors: *Pollutant transport, *Sorption, *Organic chemicals, *Model studies, *Fate of pollutants, Solubility, Waste disposal, Solvophobic theory.

A theoretical approach, based upon the assumption of predominance of solvophobic interactions, was formulated to quantitatively describe the sorption and transport of hydrophobic organic chemicals (HOC) from aqueous and aqueous-organic-solvent mixtures. In the theoretical approach, solvent-sorbate interactions (solubility) are specifically considered in order to predict sorbate-sorbent interactions (sorption). For HOC sorption from a single solvent, the HOC sorption coefficient was shown to increase loglinearly with the hydrocarbonaceous surface area (HSA) of the sorbate. For HOC sorption from aqueous-organic binary solvent mixtures, the sorption coefficient is predicted to decrease exponentially as the fraction of organic cosolvent increases. This is a direct consequence of increased HOC solubility in the binary solvent. Because sorption and mobility of HOC are inversely related, a decrease in sorption coefficient leads to an enhanced HOC mobility as the fraction of organic cosolvent is increased. A preliminary verification of the theory was performed by an analysis of published data for (i) HOC sorption by soils and sediments from water, (ii) HOC retention by reversed-phase chromatographic sorbents during isocratic elution with methanol-water binary solvent mixture, and (iii) HOC mobility on soil-TLC plates eluted with ethanol-water mixtures. USING CREAMS AND ECONOMIC MODELING TO EVALUATE CONSERVATION PRACTICES: AN APPLICATION,
Economic Research Service, Washington, DC. Natural Resource Economics Div.
B. M. Crowder, H. B. Pionke, D. J. Epp, and C. E. Young.
Journal of Environmental Quality, Vol. 14, No. 3, p 428-434, 1985. 1 Fig, 2 Tab, 21 Ref. Pennsylvania Agricultural Exp. Stn. project 2587.

Descriptors: *Soil conservation, *Model studies, *Economic aspects, Nutrient loss, Conservation, Erosion, Agricultural runoff, Nonpoint pollution sources, Conservation tillage.

Economic modeling of the impacts of soil loss from agricultural activities traditionally has been based on the Universal Soil Loss Equation (USLE). Most studies have not considered the effects of agricultural production on N, P, and pesticides in runoff. This study, involving a representative Pennsylvania dairy farm, uses the CREAMS model (Chemicals, Runoff, and Erosion from Agricultural Management Systems) to estimate surface runoff losses of soil, plant nutrients, and pesticides. The CREAMS is a continuous simulation model that allows the user to compare the effectiveness of management practices for reducing these losses in a consistent and comprehensive manner. The usefulness of the CREAMS simulation model is demonstrated for analysis of agricultural cropping activities and their impacts on losses of chemicals and soil in runoff. Linear programming was used to simulate the impacts of farm-level water pollution restrictions on farm income. Nonpoint source pollution can be reduced without necessarily reducing farm income. Farm income levels could be maintained by adopting conservation tillage practices or by changing crop rotation. Conservation tillage was found to be the most effective method for maintaining income when water pollution restrictions were imposed. Two years of corn (Zea mays) followed by 3 yr of alfalfa (Medicago sativa) was a profitable and effective rotation for controlling runoff losses. Continuous corn, at the other extreme, caused substan-

tial losses of income when restrictions were imposed. (Author's abstract)

REDISTRIBUTION OF BROMIDE BY RAINFALL INFILTRATION INTO A CECIL SANDY LOAM LANDSCAPE,
Agricultural Research Service, Watkinsville, GA.
R. R. Bruce, R. A. Leonard, A. W. Thomas, and W. A. Jackson.
Journal of Environmental Quality, Vol. 14, No. 3, p 439-445, 1985. 13 Fig, 3 Tab, 12 Ref.

Descriptors: *Bromide, *Rainfall, *Infiltration, *Soil types, Solute transport, Leaching, Erosion, Topography, Permeability coefficient.

The redistribution of bromide applied to the soil surface at selected position in a sample Cecil sandy loam (clayey, kaolinitic, thermic Typic Hapludults) landscape was measured in relation to rainfall and pedon characteristics. Three bromide application sites were located in drainageway positions and three on slope positions exhibiting different degrees of erosion. Observations of nearly 4 yr measured 4.7 m of rainfall to show that rainfall was more effective in transporting Br through drainageway pedons than those on the slopes. After 1000 mm of rainfall, half of the applied Br was above 0.6 m on the slope sites and above 1.0 m on the drainageway sites. This difference seems to relate closely to the higher hydraulic conductivity in the Bt horizon above the 1.2 m in the drainageway pedons than in the slope pedons. Also, the maximum clay zones in the Bt horizons of the drainageway sites were significantly lower than those on the slope sites and occurred about 0.5 m deeper. At the completion of this study, an elevated Br level was measured in a drainageway site between 1.5 and 2.4 m with no evidence of Br below 3.8 m. These data provide a basis for assigning solute transport characteristics to the identified variability in this and similar landscapes. (Author's abstract)

OUTFALL DILUTION: THE ROLE OF A FAR-FIELD MODEL,
Miami Univ., Coral Gables, FL. Dept. of Civil and Architectural Engineering.
D. A. Chin.
Journal of Environmental Engineering, Vol. 111, No. 4, p 473-486, August, 1985. 10 Fig, 6 Ref.

Descriptors: *Outfall, *Far-field models, *Model studies, *Dilution, Wastewater outfall, Near-field mixing, Far-field mixing, Fate of pollutants, Path of pollutants, Coastal waters.

Effluent dilutions predicted by near-field models do not realistically reflect near-field conditions in tidally influenced coastal waters since they neglect the advection of the pollutant cloud over the source. A theoretical solution has been developed for the case in which a conservative pollutant is released from a line source into a uniform unsteady flowing ambient where diffusion is only significant in the cross-stream direction. Considering the case of a sinusoidal variation of velocity along the streamwise principal axis, it has been shown that the expected concentration at a source located in a typical flow field may increase by as much as 15% per cycle over that predicted by the near-field model. A hypothetical outfall was analyzed using real data and a dispersion model which accounts for the near-, as well as far-field mixing. The near-field model was found to underestimate the average dilution at the source by about 21%. Extreme values were also underestimated. The results of this study indicate that a complete dispersion model should be used in predicting dilutions in outfall mixing zones of coastal regions. (Author's abstract)

Journal of Environmental Sciences and Health, Vol. A20, No. 4, p 395-417, 1985. 8 Fig, 1 Tab, 11 Ref.

Descriptors: *Lead, *Heavy metals, *Mississippi River, Water pollution, Path of pollutants, Metals, Fate of pollutants.

Previous investigations involving lead in the lower Mississipi River generally reported low levels, prompting the conclusion that human activity has not resulted in undesirable lead levels in the river water. Our studies reveal that of 435 samples collected between 1978 and mid-1983 from stations at river miles 266, 202, 147, 120, 75 and 49, about 9% had total lead levels exceeding the EPA allowable for drinking water. These values include one of 10,000 micro-g/l and 5 larger than 500 micro-g/l (10 times the EPA allowable). On the basis of the observed variability of lead levels in time and distance, it is concluded that (a) the high lead levels are associated with the Lutcher-Luling-Belle Chasse river stretch (i.e., river miles 147-75); (b) the problem is a result of human activity; and (c) there are mechanisms for the relatively rapid removal of lead and/or dilution of high-lead episodes as the river water flows down stream. STREAMFLOW NITROGEN LOSS FOLLOWING FOREST FERTILIZATION IN A SOUTHERN VANCOUVER ISLAND WATERSHED,
Pacific Forest Research Centre, Victoria (British Columbia).
E. D. Hetherington.
Canadian Journal of Forest Research, Vol. 15, No. 1, p 34-41, February, 1985. 5 Fig, 6 Tab, 33 Ref.

Descriptors: *Fertilization, *Nitrogen, *Forest watersheds, *Vancouver Island, *British Columbia, Fir trees, Water quality, Urea, Ammonia, Nitrates, Fate of pollutants, Nitrification, Streams.

Water quality was monitored in the Lens Creek watershed on southern Vancouver Island (British Columbia) to determine nitrogen loss following fall application of 224 kg N/ha urea fertilizer on a second-growth Douglas-fir (Pseudotsuga menziesii (Mirb.) Franco) forest. Peak nitrogen concentrations measured in two small tributary stream
14 mg/L as urea, 1.9 mg/L as ammonia, a
mg/L as nitrate. For the first 14 months, est
nitrogen outputs in excess of background a
were 5.9 and 14.5% of the total applied n
for the two subsidiary watersheds with 46 an
of their drainage areas fertilized, respec
These losses were considerably higher
amounts of less than 1% previously repor
western North America. Increased levels of
and ammonia N were short-lived, while ni
remained above background levels for the
duration. Reasons for the high nitrogen l
clude nitrification of the urea during 7 w
mild, dry weather following fertilization, p
of alder and swampy areas adjacent to the s
high soil permeability, steep slopes, and ab
above average early winter rainfall. The
sheds had been previously fertilized, but an
ence of this first fertilization on nitrog
during the present study in unknown. Lens
water quality was not adversely affected
fertilization in terms of drinking water stand
toxicity to fish. (Author's abstract)

ited works on slow intrusions, both
l and theoretical, pertain to the case of
er body, when the viscous boundary
ot have time to spread to the bottom
haracteristics time of evolution of the
all changes in the velocity of the fluid
are concentrated near the intrusion layer. More complex is the case of slow fluid flows in a shallow water body, when the boundary layers spread relatively rapidly, so that the vertical velocity gradients in any layer and bottom friction can no longer be neglected. Such a case was theoretically examined on a model of a two-layer stratified fluid. If the frontal surface intersects the free surface of the fluid or the bottom, forming a front, then the equations describing the evolution of the frontal surface are essentially nonlinear, since in the zone of the front the thickness of the corresponding fluid layer vanishes. Therefore the deviations of the frontal surface from an equilibrium position are comparable with the thickness of one of the layers and they cannot be considered small. Consequently linearization of the equations near the front is inadmissible. Nevertheless, in certain cases it is possible to obtain a number of results analytically and to compare theory and experiment. Particular concern in this work centers on the slow plane-parallel flows of a viscous incompressible two-layer density-stratified fluid in a shallow water body. (Baker-IVI)

EFFECT OF THE CONTENT OF ORGANIC MATTER IN SOIL ON LEACHING OF CHEMICAL FERTILIZERS INTO THE ZONE OF AERATION AND GROUNDWATERS,
Akademiya Nauk SSSR, Moscow. Inst. Vodnykh Problem.
M. V. Lola, N. P. Akhmet'eva, and Yu. A. Medovar.
Water Resources, Vol. 11, No. 3, p 223-227, May-June, 1984. 2 Fig, 4 Tab, 4 Ref. Translated from Vodnye Resursy, No. 3, p 68-72, May-June, 1984.

Descriptors: *Organic matter, *Soil, *Leaching, *Fertilizers, Groundwater pollution, Aeration zone, Nitrogen, Potassium, Phosphorus, Sediments.

To study the possibility of the penetration of fertilizer components into groundwaters, experiments were conducted on the application of fertilizers at rates of 100 kg/ha of active ingredient of each fertilizer. In field experiments, increasing rates of organic sediments, from 50 to 2000-3000 tons/ha, were applied to the soil. The yield of barley grain increased, and simultaneously the mobility of biogenic elements in the soil decreased. The soil application of organic sediments in amounts greater than 500 tons/ha is economically unprofitable, and technically difficult to accomplish. Application rates of organic sediments less than 500 tons/ha do not produce sufficiently high yields. The effect of organic sediments applied to the soil on its adsorbing capacity for chemical fertilizers was studied. An increase in the content of organic matter in soil led to retention of ammonium and nitrate nitrogen in the zone of aeration. Without the application of bottom sediments, the concentration of nitrate nitrogen was at the usual level found in unfertilized soil. Generally, an increase in the content of nitrogen, phosphorus, and potassium was observed in the plow layer with increased application rates of organic matter. The exception was water soluble potassium, the content of which was minimum in the variant with the maximum application rate of organic matter. A decrease in leaching of biogenic elements was noted with an increase of application rate of organic sediments, except nitrate nitrogen. (Baker-IVI)
